

IMPROVED TRACK SANDER.

Y-shaped casing is the pipe *L*, which leads to the point at which it is desired to discharge the sand Within the casing, and extending partially over the passage leading to pipe *L* is a shelf *K* In operation, when compressed air is admitted to the nozzle it forces its way past the ball *F* into the sand of the sand box *A* A portion of the air is directed backward to the jet opening *E*, producing a partial vacuum, which causes the sand that is agitated by the other jet of air to flow along the shelf *K* and thence be carried down the discharge pipe *L* The ball *F* prevents the constricted opening in the nozzle from being clogged with sand, and this constricted opening serves to reduce the fluid pressure by permitting its expansion past the ball *F*, so that a destructive sand blast is avoided thereby The inventor of this improved track sander is Mr John Henry Watters of Augusta, Ga

## BRIEF NOTES ABOUT NEW INVENTIONS.

The singing sign which has been recently placed in front of a Denver business house is a visual as well as audible means of attracting the attention of passers-by The particular sign referred to displays the word Dentists' and is of the electric flashing type The illumination of one letter follows the other, and as the lamps comprising each letter are flashed, a wooden hammer strikes one of a group of orchestral chimes There is a different bell for each letter, and the chimes represent a complete octave The combination of sounds may be varied at will with but little trouble

The illuminated elevator threshold is a new means to prevent what is a quite common form of elevator accident The elevator attendant, making hundreds of stops in the course of a day, is not always enabled to bring the car to a halt at the exact floor level, and a very slight variation is sufficient to give the passenger a jolt if not more serious injury The floor of the car being held an inch or two above that of the building is likely to trip the unguarded person about to enter the car, while persons stepping out are liable to be thrown down. The latest method of avoiding this is the insertion of a pair of plate glass lenses in the metal of the threshold, with an incandescent lamp under each. These are kept in operation all the time the car is in use. The lamps are supplied through the elevator cable in the same manner as the overhead lamps This device has been tried with eminent success in some moving-picture establishments, where the rear seats are slightly above the level of the aisle floor

The jobbing carpenter moving around from one place to another, and locating for a few days at a time in one spot, in the course of his peripatetic career is compelled to spend considerable of his time in the construction of wooden horses or trestles, which are generally so necessary for his work These things are of such an awkward shape and also that it is out of the question to carry them from point to point, so he is compelled to build them in many cases before he can proceed with his work To meet such demands, horses of steel with collapsible legs have recently been made, so that they may be readily packed up and carried from place to place The legs fold over on the back of the trestle when not in use and when being transported, and in this form they are very compact. Being of angle iron, the trestle is not heavy and is almost everlasting

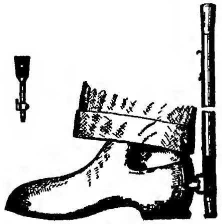
## ODDITIES IN INVENTIONS.

Hat Fastener.—The recent agitation against long hatpins has set a Yankee inventor to thinking He has arranged a hatpin which has no exposed point and which does not have to be removed from the hat, but which may be operated to engage the hair by giving it a half turn. The hatpin extends from side to side of the crown of the hat, and is provided

A NOVEL TYPE OF HATPIN

with a series of hooks or grapples sharply pointed at the ends, so that when the pin is turned they will hook into the hair Whether the hat fastener has been tried in actual practice we do not know but it seems as if there would be considerable danger of entangling the hair in the curved hooks

Device for Drawing on and Removing Overshoes.—An inventor does not have to go far afield for objects upon which to exercise his inventive faculties Even in the most commonplace matters of everyday life there is room for improvement Take, for instance, the method of removing one's overshoes the usual way of teetering on one foot while trying to kick the shoe off the other foot is most awkward, to say



DEVICE FOR DRAWING ON AND REMOVING OVERSHOES.

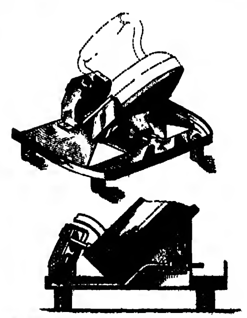
the least Recently, an inventor has devised a little attachment for the cane or umbrella, whereby one can stand firmly on one foot and steady himself with the umbrella while removing the overshoe by pressing the lug at the back of the overshoe against the attachment on the umbrella. The inventor has provided a more elaborate device to hold the overshoe in place while drawing it on. The lug at the heel of the overshoe is so formed that it can be engaged between a pair of jaw clamps, one of which is fixed while the other is spring-actuated The device is applicable to a cane, and running from the movable jaw to within a convenient distance of the head of the cane is a rod, which may be lifted to release the jaws.

Luminous Gun Sights.—When using a gun in the dark or deep twilight, it is very difficult to secure accurate aim, because the sights are invisible This difficulty has frequently been experienced by sentries,

LUMINOUS SIGHTS FOR TWILIGHT SHOOTING.

who should be able to cover an approaching enemy with accuracy, in order to secure their own safety as well as that of the camp To enable this to be done, an inventor has recently devised a gun in which the sights are luminous This is effected by means of a pair of small electric lamps lighted by batteries placed in the stock of the gun The sectional views in the accompanying cut show how the lamps are arranged The sights are formed with prisms, which at their lower ends communicate with chambers in which the lamps are located The lamps are lit only when the trigger is partially pressed, so that it is not necessary for the sentry to expose his whereabouts until he is ready to fire The sights are of such a nature that they may be used in the daytime with the lamps disconnected, a switch being provided for opening or closing the lamp circuit

Support for Electrically Heated Flatirons.—A novel support has recently been invented for electrically heated flatirons It is so arranged that the current is turned on only when the iron is on the support. The support consists of a metallic base provided with legs of insulating material and upon which is mounted, in inclined position, a plate of slate On this the flatiron is adapted to be supported, so that the head of the flatiron will slide down and bear against a block of insulating material at the rear of the base In this block are two sockets, provided with metallic clips forming the terminals of an electric current The flatiron, which is provided with the usual heating coils, has two terminal pins near



SUPPORT FOR ELECTRICALLY HEATED FLATIRONS.

the heel. These are adapted to engage the clips when the iron is in position on the slate. This completes the circuit through the coils, and serves to heat the iron As soon as the iron is removed from the stove, the circuit is broken, and there is no waste of current or dangerous overheating liable to cause a fire.

## RECENTLY PATENTED INVENTIONS.

### Electrical Devices.

TELAUTOGRAPH INSTRUMENT.—A. L. GOLDEN, Oakland, Cal. This instrument is for use in copying written matter or drawing by electro-magnetic means. An object of the invention is to provide a device by means of which a person at one station may write a letter, sign his name or execute a drawing, which a similar device will reproduce at another station in the form of an exact duplicate.

### Of Interest to Farmers.

SIX-HORSE DRAFT MECHANISM.—H. MASSMAN, Kentland, Ind. This invention has reference to draft mechanism or draft gear enabling a number of horses or similar draft animals to be attached to a plow or other implement, and provides a construction which will equalize the leverage and pulling force exerted by the different animals.

GRAIN SPREADER AND FEEDER.—A. CLARK, Portland, Ore. The improvement relates to a device applicable to the feed or supply table of threshing machines and machines of a like type, being especially designed for use in connection with the feeding of headed grain, which, even under the most favorable conditions of service, frequently "slug" the cylinder.

CHURN.—W. F. S. SMITHDEAL, Salisbury, N. C. In general the invention may be defined as consisting of a pyramidal frame having head blocks spaced apart, the blocks having slots in vertical alinement entering the edges from one side of the frame, a hand lever fulcrumed at the opposite side of the frame and having a cross arm, a dasher shaft, removably journaled in the slots and having a belt wheel and a belt detachably connected to the arm and passing around the wheel.

### Of General Interest.

COMPOSITE BEAM STRUCTURE.—W. P. FRANCIS, Pensacola, Fla. Among the principal objects here is to provide a construction wherein is combined the tensile strength of metal formation with the immobility of masonry, to provide a composite structure of metal and masonry whereby the metal members are arranged in truss form, to provide a fireproof construction for a carrying beam.

LINE-CLINOMETER.—E. H. HOLDEN, New York, N. Y. This improvement comprehends a line clinometer provided with a telescope and a level associated therewith, the telescope being adapted to turn in a substantially vertical plane, and means including a vernier and a level for measuring the extent of inclination of the telescope from a given real or imaginary line.

ELECTRIC FURNACE.—H. W. HIXON, Philadelphia, Pa. More particularly this invention relates to those furnaces used in the smelting of zinc ores. An object is to provide a furnace in which the zinc is fed in at the top, which is kept closed by means of a top of double construction so arranged that an upper door may be opened and a charge fed in while the lower door is shut.

### Hardware and Tools.

PADLOCK.—A. M. H. DE BRUYCKER, New York, N. Y. This invention relates to locks having a main bolt formed of hook members, such, for instance, as shown and described in the Letters Patent of the U. S., formerly granted to Mr. De Bruycker. The aim is to provide a padlock having both sides of the hasp notched for engagement by the hooked members of a bolt actuated by key controlled means.

NAIL-HOLDER FOR HAMMERS.—H. SCHNEIDER, New York, N. Y. The holder is arranged to hold the nail and to start it prior to driving the nail home, and to readily accommodate nails of different length. For this purpose the head of the hammer is provided with integral abutments located different distances from the face of the hammer head and retaining means in alinement with the abutments for temporarily holding a nail, the head of the nail abutting against the corresponding abutment.

### Heating and Lighting.

SHOCK ABSORBER FOR TUNGSTEN LAMPS.—F. SCHWARTZ and L. KLEINMANN, New York, N. Y. This invention is particularly useful in connection with electric lamps such as tungsten lamps having fragile filaments. The purpose is to provide a hanger having a shock-absorbing device for supporting the lamp, which will operate to prevent the transmission of a jar or shock to the lamp, which might be otherwise transmitted from the ceiling or wall.

CANDELABRUM.—C. YOOS, New York, N. Y. This candelabrum is such as used in churches, chapels and similar places where candles are left burning continuously. A special construction operates to bring about a complete consumption of the candle. The invention resides partly in the nature and form of the bobache or cup which supports the candle. The construction is such as to prevent the accumulation of wax or candle grease upon the parts.

### Household Utilities.

TRAP.—M. L. FRANCIS, Onida, S. D. In this instance the invention relates to traps for use in catching insects, and resides more particularly in a trap for flies and the like, comprising apertured screens adapted to entrap the insects, and so constructed as to permit of the same being removably used on screen doors, window screens and like protections.

WASHBOARD.—D. STEIN, New York, N. Y. This improvement relates to metal washboards. In this board the inventor forms the entire frame, that is, the side bars and the top or transverse member, all of a single piece of channel iron, and the width of the groove in the channel is such that the corrugated metal rubbing surface is firmly held therein. The board is reversible.

MOP HEAD.—W. H. ZACHRY, Atlanta, Ga. In this device the improved head is simply constructed, is efficient, and all the operative mechanism is concealed by the cover plate. When not in use the parts may be separated, to permit the threads to dry, thus preventing rust, and increasing the longevity of the head. As an article of manufacture, the device could possibly be marketed without the handle.

### Machines and Mechanical Devices.

APPARATUS FOR BEADING OR TURNING OVER BOILER TUBES.—H. E. A. GALLON, 22 bis Rue du Cours, Sotteville les Rouen, France. This improved apparatus contrary to those of former invention enables work to be done on plates which are out of shape and in oval holes without any trouble, to obtain different sections of flange on tubes which may be of different diameters and of producing on the work rolling forces which are capable of insuring perfect connection of surfaces which are to maintain damaged tube plates fluid tight.

CUE TIPPING MACHINE.—G. MAHONEY, Iowa City, Iowa. This machine is for use in forming and trimming the tip of a cue or the like. The device is easily manipulated and quick and accurate in its operation. It consists of a plurality of cutting, trimming and filing wheels, driven by a suitable means and juxtaposed to suitable work supports or rests.

CLOTH CUTTER.—M. LANGMAN, New York, N. Y.—The purposes here are: To keep the blade constantly sharp by operating upon it for this purpose while it is in action cutting cloth. To throw the sharpening mechanism out of working relation at the will of the operator without moving it from the blade and parts associated therewith. To provide various details of construction for improving the general efficiency of cloth cutters.

COIN DIRECTOR FOR VENDING MACHINES.—W. ASBURY, New York, N. Y. The object of this invention is to provide a coin director disposed in the coin chute of a vending machine, which will alternately direct coins in opposite directions. An object is to provide means which will permit coins of less than predetermined diameter to pass through an opening in the coin chute so that they will not engage the coin director.

### Prime Movers and Their Accessories.

STEAM-GENERATOR.—I. WICHROWSKI, 622 Myrtle Avenue, Brooklyn, New York, N. Y. This device has a flat rectangular partitioned compartment disposed directly over the furnace, with communication in the partition one compartment subdivision for use as a superheater, there being a steam dome in communication with the former and a water supply in communication with the boiler, the boiler being disposed over the flue which has a continuation which is disposed in the steam dome. A valve is provided in the communication between the superheater and steam dome. The inventor gives information that steam generates rapidly on high pressure and temperature. It is particularly adapted for steam turbines.

STEAM TURBINE.—T. FALVEY, London, England. This invention relates to improvements in turbines of the kind previously invented by Mr. Falvey wherein the rotor consists of a disk carrying upon one of its faces concentric annular series of tangentially inclined vanes which alternate radially and are adapted to co-act with similar series of vanes reversely inclined, carried upon the opposed face of the stator of the turbine, the steam passing radially outward through the successive series of vanes into a peripheral exhaust channel in communication with the exhaust pipe.

SAFETY-GATE.—E. KRANCHER, New York, N. Y. This invention relates to safety gates, suitable more especially for use upon cars and similar railway vehicles, the more particular purpose being to prevent persons from passing from one car to another while the train is rounding a curve, or at least to warn such persons of this danger.

DEPOSITING BOX AND TIME STAMP.—C. A. NAUCK, Little Rock, Ark. This invention has reference to time recorders, and its object is to provide a new and improved depositing box and time stamp, designed for use in receiving articles such as envelops filled with transfer tickets as used by railways, the device providing the article stamped indicating the time of day or night, and depositing the accumulated articles in a box for convenient removal after a day's work.

COUPLING FOR AIR-BRAKE PIPES.—L. A. PETERSON, Hannaford, N. D. The improvement relates to means for reliably coupling together the sections of an air-brake supply pipe that extend from car to car throughout a train, and particularly to such appliances as are provided for conveying air under pressure to the air-actuated brakes of a train of freight cars.

### Railways and Their Accessories.

TRAIN-ORDER HOLDER.—A. W. VICE, Savannah, Ga. This device is of book form, having means to retain the orders stretched out of the inner side of either cover and present the same, when the holder is open, in a visible and accessible position, thus avoiding the handling, folding and careless pocketing of the orders by trainmen and insuring a careful and frequent reading of the orders, the holder being preferably removably supported on a bracket with the latter arranged to cause the covers of the holder to swing apart and remain open when the covers are unlatched.

### Pertaining to Recreation.

AMUSEMENT DEVICE.—J. J. TARANOS, New York, N. Y. More specifically the invention relates to an amusement device having movable hurdles or obstacles, and means for actuating the same so that a child can jump or skip over the hurdles as these travel, there by providing a substitute for the ordinary jumping or skipping rope.

### Pertaining to Vehicles.

RUNNING GEAR FOR VEHICLES.—D. H. MASTERS, Cliff, New Mex. The details of construction for the running gears more particularly for automobiles adapt said gears to reliably coöperate for swinging the ends of both axles simultaneously an equal degree toward each other at one side of the vehicle and correspondingly diverging their opposite ends at the other side thereof, whereby full control of the turning either side thereof is insured and danger due to loss of control is avoided.

### Designs.

DESIGN FOR A CIGAR OR CIGARETTE HOLDER.—A. Q. WATSON, New York, N. Y. This design includes two figures of a holder. Both are ornamented their entire length beyond the mouth end by an attractive plant and flower design. The particular difference is in the mouth ends of the holders one being rather straight and slightly flattened and the other narrowed into a bottle neck shape and then broadening at the orifice of the mouth end.

DESIGN FOR AN ORNAMENT FOR GARMENTS.—A. IALLAND, New York, N. Y. This ornamental design represents a long bodied animal without limbs of any kind the body tapering from a very bushy head to the tail, which spreads out at the end.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th, 1909, or will be sent by mail on request.

(12228) E. A. P. says: Does an article weigh the same at the equator as at the poles of the earth? If not why not? How much difference would there be? A. For two causes a body will weigh more at the poles than at the equator. One is that it is nearer the center of the earth; the other is that the rotation of the earth on its axis lightens bodies at the equator but not at all at the poles. This is called centrifugal force. The weight of a body at the poles is 1/289 of its weight at the equator or about 5 pounds in 1,000 pounds.

(12229) W. H. B. says: To photograph the vibrations of the diaphragm of a phonograph by a narrow beam of light thrown on a photographic film say one half inch in width contained on two spools and moving in unison with the phonograph, said film to be afterward developed and then used as a reproducer on a photographic machine the wires of which have a small selenium connection, and a narrow beam of light being thrown through the film of the selenium and connected with the ordinary telephone reproducer. The vibrations could be photographed in a number of ways. A small mirror could be fastened to the phonograph and reflect the beam of light on the film. A diaphragm could be made so that it would open and close in unison with the vibrations. In fact there are a great many different ways, as I have said before, in which this could be accomplished, but whether the vibrations would be of such a nature, or the celluloid film pure enough so that the interruption of the electric currents produced by the light shining through these vibrations would make a practical instrument, is beyond me without working it out. The drawbacks to the present phonograph are the shortness of the record and the scratching of the needle. If it were possible to transfer the vibrations of sound into light and photograph them on the film, as I have stated above, the period of the phonographic record could be greatly lengthened, and of course there would be no scratching from the needle itself. A. We should not dare to say that a photographic film could not reproduce sounds, but it does not seem to us to be probable that it could do so. It would seem to us almost certain that selenium could not vary rapidly enough to produce a record of a sound. Certainly if a mechanical shutter were worked fast enough to be in unison with the vibrations the shutter would emit the same tone as the sound and it is not obvious how a shutter could change its rate of opening and closing to keep in unison with all the tones of the sounds. There is a phonograph which employs magnetism and magnetizes a rapidly moving wire so that it will reproduce speech or music which has been said or sung into it most perfectly and without any rasping or disagreeable sounds such as all other phonographs have. A length of wire can be used which will permit a whole discourse of an hour to be taken upon it.

(12230) A. M. asks: While I was in New York a few years ago taking in the statue of Liberty, I was told that the copper sheathing of the statue was insulated from the steel framework to protect the one metal from the other in some action of destruction. I have noticed that some lightning rod manufacturers use a combination of steel and copper and the thought struck me that the same destruction would occur in such rods. Will you be kind enough to explain what action causes the destruction and to what extent? A. Copper and iron are two metals between which an electromotive force is set up when they come into contact with each other producing an electric current. This current causes an eating away of one of the metals and thus the statue of Liberty would be gradually destroyed if the copper sheets were riveted directly to the iron framework. The action is very slow but the statue was intended to endure for a very long time. The joints of a rod of these two metals would in time become loose for the same reason. This process is called electrolysis.

(12231) J. L. B. asks: Will you please tell me how to transform a 110-volt alternating current to a direct current of 8 or 12 volts? I wish to use the electric light current in my house to ring door bells and to operate small motors. A. You will find the descriptions of rectifiers in our SUPPLEMENTS 1748 and 1844 price ten cents each. One of these will give you direct current for ringing a door bell.

(12232) A. R. K. says: Will you please tell the difference in the quality or character of the primary and secondary current of the induction coil? The current seems to be intensified or augmented but what to volts amperes or electromotive force? Would the secondary current operate an electromagnet? A. In an induction coil such as is used for producing sparks or working X-ray tubes and wireless telegraph apparatus the primary current is of low voltage and is interrupted many times a second. It is an interrupted direct current. The secondary coil has a current of much higher voltage and if the terminals are quite a distance apart and a condenser is used the secondary current is also always in the same direction. The terminals of the secondary are plus and minus but do not change their sign unless the direction of the primary current is changed or reversed. The secondary current will not usually operate a motor nor can it be used on an electromagnet.

(12233) G. T. says: Why is it that the winds are not utilized as a source of power for practically all purposes? Why for instance could I not light and heat my house with electricity derived from the force of the winds? A. There is no reason whatever why you should not heat and light your house with wind power if you had enough wind and enough plant. The only reason why windmills are not more used is that there are few places where wind is sufficiently constant to provide continuous power and if no auxiliary engine is used to run the plant when there is no wind the capacity of both windmill and generator must be greatly in excess of normal requirements in order to generate enough power when the wind blows to serve for longer periods of calm. The storage battery capacity must be also very great. Probably the most convenient and cheap way is to have a large tank (in an attic or the top of a barn or on a hill) of capacity sufficient to run a water motor driving the generator for three or four days at least and a windmill pump of sufficient capacity to fill the tank in a day's continuous pumping or less.

(12234) F. L. P. writes: I know that a person has more or less electricity in him but I have a question about myself. I am a school teacher. When writing on an ordinary plaster blackboard I generally receive an electric shock and a snap is heard. My classes recite in different rooms and this occurs in two but not in the third. It occurs in two rooms that are adjoining, but always on the south walls only. Could it be defective wiring in our lighting system? Could defective wiring give that kind of a shock? Is plaster a good conductor? Isn't it rather a poor conductor? I am generally able to discharge it

at the second touch if not the first and do not always notice it at the first touch in opposition to the defective wiring. I have been able to find no one else in the class who ever notices the same thing although they can see me draw back my hand when I receive the shock. Again I have noticed the shock and heard the snap when I passed something say a pencil from my hand to that of a student. A. It is doubtless true that some persons can generate sparks of electricity more easily than others. You seem to be one of those who have that power. We have always supposed that it was due to an unusual dryness of the skin so that the friction of the feet on the carpet or floor produced electrification to an unusual degree. It is not uncommon in cold dry weather for a person to feel a slight pricking from a spark of electricity when he touches a wall or some object. People can light a gas jet in that way. We should not say that people have electricity in them any more than the earth has electricity in it. Electricity or the ability to become electrified is common to all things. Insulate anything and it can be electrified. It is not necessary to suppose that the electric light wiring has anything to do with the phenomena. If that were defective you would have trouble with the lights.

(12235) W. H. McF. says: Kindly explain how an engine makes a curve when the outside rail is longer than the inside. A. When an engine on rails rounds a curve centrifugal force carries it toward the outer rail to some small extent causing the wheels which are tapered or cone shaped to run on a larger circumference on the outer and a smaller circumference on the inner rail. The tapering of the wheels is not however sufficient to provide for all the differences between the length of the inner and outer rails and has lately been reduced and the remaining difference is overcome by the slip of the inner wheels on the rail when the pressure of the outer wheels is greater.

(12236) J. F. says: Could you give me a plain rule or formula for computing the time of rising and setting of the sun moon and stars through your Notes and Queries or otherwise, or refer me to a book that contains such a rule or formula? A. The times of the rising and setting of the sun moon and stars are found from spherical trigonometry using the latitude of the place and the declination and right ascension of the heavenly body whose times are to be computed. We do not know any short method for getting the result. The methods are briefly given in Young's General Astronomy, which we send for $4 post paid.

(12237) H. C. M. says: Will you kindly give me information on the following point? Is it possible and if so by what formula to compute the volume of a gas passing through an aperture of known size having given the density of the gas its pressure and the pressure of the atmosphere into which it is discharging? A. The theoretical velocity in feet per second of the flow of gas or any fluid or liquid through an orifice is $v = \sqrt{2gh} = 8.02\sqrt{h}$ in which $h$ equals the head or [illegible] height of a column of the fluid in feet required to produce the pressure of the fluid at the level of the orifice. $H = \frac{v^2}{2g}$. The quantity of flow in cubic feet per second is equal to the velocity multiplied by the area of the orifice in square feet and also multiplied by a coefficient of flow which takes into account the vena contracta of the flowing stream and the friction of the orifice, etc. Dr. Julius Weisbach gives the following coefficients for flow from a vessel of pressure $p1$ into a reservoir or atmosphere of pressure $p2$ for circular orifice of 1 centimeter diameter. When the ratio $p1 - p2$ is 1.05, 1.09, 1.43, 1.65, 1.80, 2.15, coefficient of flow is 0.555, 0.589, 0.602, 0.721, 0.754, 0.788.

(12238) N. V. says: 1. I would like to have a copy of the naval telegraph code. A. We would suggest an application to the Secretary of the Navy for a copy of the naval telegraph code. 2. How many batteries (dry) to run a 10 candle power incandescent lamp? A. We cannot tell you how many dry cells will be required to run a 10 candle power incandescent lamp. Take enough to furnish the voltage in series at 1.4 volts per cell and as many series as will bring the lamp to full brightness. 3. Can you tell me how to prepare woods for collections (showing a cross grain face, a bevel face, a longitudinal face and bark)? A. Woods are prepared for museum collections by sawing the sections as you describe and smoothing them carefully to bring out the grain. One half of each part is usually varnished to show its appearance when polished.

(12239) F. N. L. asks: As your paper is on our files here I take the liberty of submitting a bet that has been made here for your decision. A bets that at the equatorial line the sun rises and sets at 6 A. M. and 6 P. M. B bets that the changes in time vary same as here in Hawaii. A personal note as to who wins this bet will greatly oblige. A. We do not decide bets. Our Hints to Correspondents have for a long time stated this plainly. We will say that as viewed from the equator of the earth the poles of the heavens are upon the north and south points of the horizon. All circles of daily motion are perpendicular to the horizon and are bisected by the horizon. Every heavenly body is half of the day above the horizon and half of the day below the horizon. Perhaps you can tell from this at what hour of the day the sun must always rise and set as seen from the equator.

## NEW BOOKS, ETC.

**RHODES'S DIRECTORY OF PASSENGER STEAMERS.** London: George Philip & Son, Ltd., 1910. 12mo., 387 pp. Price, $1.

This is a very valuable book for all who are interested in any way in shipping. It gives a list of companies with the names of the vessels under each; then comes a directory of passenger steamers giving the length, breadth, depth, horse-power, etc., of all vessels. The writer has found this book of great value in comparing tonnages and horse-power in disputed questions which have arisen. There are a number of excellent illustrations in the front of the book. The book is printed on light weight paper rendering it very convenient for reference. It is attractively bound.

**THE HISTORY OF THE LOGARITHMIC SLIDE RULE AND ALLIED INSTRUMENTS.** By Florian Cajori, Ph.D. New York: Engineering News Publishing Company, 1909. 12mo., 126 pp. Price, $1.

Of the machines for minimizing mental labor in computation no device has been of greater general interest than that of the slide rule, and few instruments offer a more attractive field for historical study. The present monograph deals with the history and development of the slide rule in various countries. There is too a complete list of all the slide rules designed and used since 1800; there is also a bibliography of books on the slide rule and altogether the work is a most interesting one. The author is to be congratulated on the production of a unique book.

**THE ENGINEERING INDEX ANNUAL, 1909.** Compiled from the Engineering Index, published monthly in the Engineering Magazine during 1909. New York and London: The Engineering Magazine, 1910. 8vo., 471 pp. Price, $2.

For the past twenty-six years the Engineering Magazine has been publishing a valuable index of engineering and technical literature, and for the last four years the index has appeared annually. In the present volume the classifications have been amplified and cross references freely used to assist a person in finding the literature he desires. The index covers a long list of periodicals three-fourths of which are printed in English while the others are German, French, Spanish, Italian and Dutch. A brief description is given in each case to define the scope and purport of the article.

**TECHNISCHER FÜHRER DURCH WIEN.** Herausgegeben vom Oesterreichischen Ingenieur und Architekten Verein. Redigiert von Ing. Dr. Martin Paul, Stadtbauinspektor. Wien: Verlag von Gerlach & Wiedling, 1910.

The general plan of this book seems to us most admirable. It starts with "The General Development of the City of Vienna," under which general title are discussed geology and climate, hydrography, building material, statistics and government, organization of the technical bureaus, technical and industrial societies and city development. The second division under the general title of Engineering Works includes papers on traffic, postal, telegraph and telephone service, streets and squares, drainage, water supply, illumination, bridges, water works, parks and cemeteries, abattoirs and provision houses. The third division under the general title of Architectural Works discusses the development of Viennese architecture within the last fifty years, buildings for art purposes, buildings of the imperial court, administration buildings, educational buildings, hospitals and asylums, military structures, club houses, museums, exchanges and business houses, exposition buildings. The fourth division on plastic art and art collections, discusses monuments and public buildings, collections and libraries. Under the fifth and last division the general industrial activity of the city is discussed.

**THE FLOW OF WATER.** D. Van Nostrand Company, 1909. 8vo., 228 pp. Price, $3 net.

The present work is the outcome of a series of investigations begun several years ago with the object of finding a simple expression for the phenomenon of flow in irrigation channels. The author hopes that his work will prove of interest and value to the student and useful to the practical engineer. He also hopes that it will stimulate further research and thus tend to widen the field of hydraulic knowledge.

**THE HISTORY OF THE TYPEWRITER.** By George Carl Mares. London: Guilbert Pitman, 1909. 8vo., 320 pp.

There are surely few people nowadays who are not acquainted with the typewriter either directly or indirectly but how many are aware that some three hundred different forms of writing machines have made a bold bid for public favor since the introduction of the first practical machine in the early seventies? In the "History of the Typewriter," in the compilation of which the author has been occupied for upward of five years, is presented for the first time in English literature a complete record of the invention and development of the writing machine. In the 320 pages nearly 200 machines are described with the aid of 230 illustrations—from the Mills typewriter of 185 years ago to the adaptation of typewriting to the uses of wireless telegraphy. In this volume the Beach typewriter, invented by the late A. E. Beach, comes in for a proper share of attention.

**INSECT WONDERLAND.** By Constance M. Foot. New York: John Lane Company, 1910. Price, $1.25 net.

The kind reception given to the author's little book entitled "Science Through Stories" emboldened the writer to choose for the subject of this volume some simple facts concerning the insect world, and she has selected one or more specimens of each of the seven great orders of the insect world according to the Linnean system of division.

**THE CARE OF TREES IN LAWN, STREET AND PARK.** By B. E. Fernow. New York: Henry Holt & Co., 1910. 392 pp. Price, $2 net.

The author may be well said to be the father of forestry in the United States, and those who have followed him are very deeply indebted for the splendid foundation which he laid. The book belongs in the American Nature Series. Written for amateurs by a forester, this conveniently arranged volume furnishes information such as the owner of trees may need. Trees in place may be rendered almost imperishable by proper care and attention and the author gives details of the best methods of caring for the health of trees, transplanting, combatting diseases and insects, etc. There are systematic and exhaustive lists of trees and shrubs fit for ornamental planting with helpful notes on their adaptations.

**IGNITION TIMING AND VALVE SETTING.** By Thomas H. Russell, M.E., LL.B. Chicago: The Charles C. Thompson Company, 1909. 16mo., 223 pp. Price, $1 in cloth, $1.50 in leather.

This is a comprehensive illustrated manual of self instruction for automobile owners, operators and repair men. The following are the contents: Electrical Ignition for Motor Car Engines, The Magneto System, Another View of Ignition, Magneto Ignition, General Summary of Ignition, Ignition Faults and Hints, Induction Coils, Timing Ignition, Valves and their Function and Valve Setting.

**INDIAN BIRDS.** Being a Key to Common Birds of the Plains of India. By Douglas Dewar. London and New York: John Lane Company. 16mo., 228 pp. Price, $2 net.

The object of this book is to enable those interested in Indian birds to identify them at sight. There are several good systematic works on Indian ornithology, but the systems presuppose that the reader has the specimen in his hand and is enabled to examine it leisurely feather by feather. To do this it is necessary to kill the bird in question, a procedure which gives pain to many and gives pleasure to very few. The method which the author employs is to classify birds according to their habits and outward appearance. Each bird has a color and most birds possess some anatomical peculiarity such as a crest, a long tail, long legs, etc. When the reader thinks he has located a bird he should turn to the descriptive list which composes Part II of the book. This will serve to confirm or correct him in his identification.

**OUR SEARCH FOR A WILDERNESS.** By Mary Blair Beebe and C. William Beebe. New York: Henry Holt & Co., 1910. 8vo., 408 pp. Price, $2.75 net.

This volume is an account of two trips made by Mr. and Mrs. Beebe into tropical wildernesses. The first was undertaken on a small Venezuelan sloop with which they penetrated far into the unknown Mangrove jungles, north of the Orinoco Delta, peopled principally by monkeys, scarlet ibises, and huge Anacondas. This trip ended at La Brea—the great lake of pitch—at a most critical time, when the American company had just been ousted by Castro and Venezuelans put in charge. The second search was in the Wilderness of British Guiana, where birds and animals, gold mines and Carib Indians all contributed continual interest and excitement. This pioneer exploration by an ornithologist and his wife reveals the tropics as far more delightful and bearable than the writings of most travellers would lead us to believe.

**EXPORTERS' ENCYCLOPEDIA. 1910 Edition.** New York: Exporters' Encyclopedia Company, 1910. 778 pp. Price, $5.

The Exporters' Encyclopedia is now in its sixth year and is recognized as a standard authority among export shippers, and has the strong indorsement of all the transport lines, manufacturers, etc., engaged in export trade. The "correction notes" are published in the Exporters' Review and are sent to each subscriber about the 15th of the month. This enables the book to be kept up to date until a new issue is ready.

**A FORMULA BOOK OF ENGLISH OFFICIAL HISTORICAL DOCUMENTS.** Part II. Ministerial and Judicial Records. Edited by Hubert Hall, F.S.A. Cambridge: University Press, 1909. 8vo.; 229 pp. Price, $2.50.

# INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending May 10, 1910,**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

Abrading machine, J. Heinz .... 957,674
Accordion, J. J. Neumann .... 957,414
Adding machine, C. A. Darr .... [illegible]
Adjustable wrench, C. P. Johnson .... 957,314
Advertisement holder, H. F. Berkebile .... [illegible]
Agricultural implement, J. Herman .... 957,670
Agricultural implement seat, C. Christensen .... 957,421
Aim director, J. C. Barnes .... [illegible]
Air brake system, electropneumatic, G. Macloskie .... 957,387
Airship, R. Gendts .... 957,305
Aluminium fluorid and other aluminium compounds, making, F. A. Emanuel .... 957,784
Ammonia, making, C. Bosch .... [illegible]
Anchor, J. W. Neal .... [illegible]
Anchor, J. E. Wilde .... [illegible]
Anchors, guy wire connection for land, F. M. Allen .... [illegible]
Antifreezing tank, L. Heisel .... [illegible]
Arch plate, removable water holding, C. M. Feldmann .... 957,950
Artist's sketching outfit, W. P. Silva .... [illegible]
Autographic register, H. Konerman .... 957,447
Automobile driving gear, F. J. Rivers .... [illegible]
Automobile heating appliance, C. A. Prescott .... 957,353
Automobile radiators, filler for, E. L. Thomas .... 957,814
Automobile rim, J. Hamilton .... 957,672
Automobile transfer turntable, M. A. Baker .... [illegible]
Baby jumper, I. K. Gurley .... 957,419
Bark band hook, T. G. Peeples .... [illegible]
Bag and twine holder, C. B. Hedge .... 957,567
Bag holder, R. Bush .... [illegible]
Ballast unloader, King & Barnhart .... [illegible]
Barber's chair, hydraulic, H. H. Ross .... [illegible]
Barge header, W. E. Alley .... 957,488
Barrel bodies, making bilged, W. H. Decker .... 957,457
Barrel scrubbing machine, A. Danner .... 957,609
Battery charging and discharging system, L. Fiedler .... 957,321
Bearings, lubrication of thrust, Parsons & Turnbull .... 957,797
Bed, folding, J. Naugle .... 957,340
Bedstead attachment, F. W. King .... 957,422
Belt conveyer, M. C. Disney .... [illegible]
Bending machine, T. H. Kane .... [illegible]
Bending machinery, J. F. Gail .... 957,302
Binder, loose leaf, T. Brazil Dimon .... [illegible]
Bit brace, E. E. Marks .... [illegible]
Blotter for penholders, rotary, Hare & Wiane .... 957,320
Blower, fan, N. Higgins .... [illegible]
Boat, H. W. Vaniman .... [illegible]
Bobbin, T. P. Walsh .... 957,925
Boilers and the like, furnace of steam, W. H. Postlethwaite .... 957,810
Book marker, J. Jackson .... [illegible]
Book or pad manifolding, D. I. Maxwell .... [illegible]
Bottle, L. B. Steel .... [illegible]
Bottle cleaning machine, brush, I. Burkhart .... 957,301
Bottle holder and lock, milk, M. C. Randolph .... 957,712
Bottle washing and draining machine, Kyle & Waugh .... [illegible]
Box, H. E. Walter .... [illegible]
Bracket for structural work, F. A. Winslow .... [illegible]
Brake beam, C. H. Williams, Jr. .... 957,399, 957,400
Brake head, adjustable, L. Porter .... [illegible]
Brick handling machine, R. I. Penfield .... [illegible]
Brick machine, G. W. Bond .... [illegible]
Broom holding device, H. W. Harrison .... 957,765
Brush, H. W. Haney .... 957,831
Brush making apparatus, H. D. Purdee .... [illegible]
Buckle, trace, W. M. Giffee .... [illegible]
Buffing machine, J. F. Gail .... [illegible]
Buffing machinery, J. F. Gail .... [illegible]
Bug and worm killing machine, J. Thorlvedt .... [illegible]
Building blocks, manufacture of, Kortling & Jaenisch .... [illegible]
Buildings, constructing foundations of, J. Brochard .... 957,944
Burglar alarm, W. G. Tillman .... [illegible]
Burner, O. M. Graves .... [illegible]
Butter worker, E. Wells .... [illegible]
Cabinet, extensible, J. Haynes .... [illegible]
Cabinet for stationery, F. W. Bliss .... [illegible]
Cabinet, hanging, J. Gaft .... [illegible]
Cable clip, T. J. Baugh .... [illegible]
Calender machine attachment, J. Stuart .... [illegible]
Cam mechanism, H. Wyman .... [illegible]
Can antibuckling press, J. B. Frost .... [illegible]
Cane stripping mechanism, T. J. Peters .... [illegible]
Car brake, Graham & Lib .... [illegible]
Car door lock, Quinn & Clifford .... [illegible]
Car, dump, A. Lipschutz .... [illegible]
Car fender, J. E. Barnley .... [illegible]
Car, passenger, H. H. Adams .... [illegible]
Car, railway, R. M. Mishett .... [illegible]
Car replacer, Best & Scott .... [illegible]
Car underframe, W. P. Bettendorf .... [illegible]
Carbureter, F. W. Brady .... [illegible]
Carving machine, D. E. Saletross .... [illegible]
Casket, N. Svoboda .... [illegible]
Caster, ball, D. E. Carter .... [illegible]
Centrifugal machine, Roberts & Gibson .... [illegible]
Chair, W. E. Gordon .... [illegible]
Chairs, blower for rocking, E. G. Bates .... [illegible]
Chalk sharpening device, A. Brunts .... [illegible]
Check, baggage, J. M. Dallbache .... [illegible]
Check book, H. E. Lutz .... [illegible]
Checkrein holder, O. A. Mouton .... [illegible]
Chimney draft, device for varying, Tennismann & Copping .... [illegible]
Chimney protector or shield, T. J. Cashman .... [illegible]
Chuck, automatic pneumatic, H. M. Bosch .... [illegible]
Chuck, tool, J. S. Fray .... [illegible]
Churn, W. S. Pettit .... [illegible]
Churn, J. M. Hopkins .... [illegible]
Cigar tip cutter, T. P. Pryor, Jr. .... [illegible]
Circuit breaker, C. T. Henderson .... [illegible]
Circuit breaker, automatic, C. T. Henderson .... [illegible]

Chain, [illegible] J. W. Merrill [illegible]
[illegible]
[illegible] and [illegible] bar, combination, [illegible]
[illegible]
[illegible] E. Wilson [illegible]
[illegible] G. [illegible] 957,[illegible], 957,[illegible]
[illegible] Baker & Pierce [illegible]
[illegible] Wirts [illegible]
[illegible] frictional and positively locking, A. Latham [illegible]
[illegible] Burgess & Remington [illegible]
[illegible] and train pipe connection, angle, M. A. [illegible]
[illegible] H. F. Christiberg [illegible]
[illegible] M. Ebble [illegible]
[illegible] W. L. Murphy [illegible]
[illegible] E. R. Lambie [illegible]
[illegible] building construction, form for, A. P. Fisher 957,414
[illegible] reinforced, F. R. Meyer 957,344
[illegible] reinforced, H. Greger [illegible]
[illegible] vessel for building construction, metal reinforced, A. [illegible] [illegible]
[illegible] L. R. Alberger 957,175
[illegible] fluid substances, A. G. Kalb, 957 [illegible], 957,[illegible]
[illegible] plant and air pump, steam, W Weir 957 [illegible]
[illegible] apparatus for fluid or semi-fluid substances, R. Schou [illegible]
[illegible] folding poultry, Trumpold & Koerner [illegible]
[illegible] or crate, folding, Trumpold & Koerner [illegible]
[illegible] malts and [illegible], treating [illegible], H [illegible] 957 221
[illegible] E. F. Poste [illegible]
[illegible] collapsible, C. C. Crowley [illegible]
[illegible] O. M. Rowland 957,381
[illegible] cover and bust supporter, combined, Marx & Mayer 957,617
[illegible] J. E. Williams [illegible]
[illegible] split lap preventer for, H. H. Whitehead 957 450
[illegible] E. Marek 957 [illegible]
Crate, folding, A. J. Parmeter 957 [illegible]
Cross slide operating mechanism, H. B. Lester 957,224
Cross tie, metallic, Cole & Candler 957,497
Culinary utensils, alarm device for, P. O. [illegible] 957 [illegible]
Cultivator, J. P. Meyers 957,[illegible]
Cultivator attachment, C. Bell 957,879
Cultivator attachment, swivel action, J. T. Foulke 957,[illegible]
Cultivator, hand, E. Piggott 957,[illegible]
Current controller, B. H. Parker 957 816
Current motor, T. J. Steele 957,[illegible]
Current motor, alternating, V. A. Fynn, 957,[illegible], 957,[illegible]
Curtain fixture, H. R. Keeley 957,[illegible]
Cutting machine, J. H. F. Clifton 957 747
Cylinders, making toothed, E. J. O'Brien 957,440
Cylinders, pressure equalizing mechanism for, U. W. Nistle 957,341
Dashboard, vehicle, J. F. Jacquet 957,[illegible]
Decanting oils and liquids, tilting appliance for, White & Robertson 957 [illegible]
Decoy, C. A. Cunningham 957,780
Dental cuspidor, I. E. Mair 957,471
Dentistry impression tray for, M. M. Kerr 957,[illegible]
Derrick, J. McVeigh 957 [illegible]
Desk, I. M. Tindall 957,[illegible]
Desk and seat, combined school, T. Kundtz 957 436
Disinfectant holder, C. J. Walz 957 449
Display case, D. S. Forchheimer 957 461
Display machine, J. S. Anderson 957 460
Distilling apparatus, G. Lacaay 957,618
Door closer, H. J. Wents 957 [illegible]
Door, grain, A. A. Kramer 957 434
Door operating means, sliding, P. Wheeler 957 284
Door operator, electric, T. Nakahara 957 572
Door stop, E. Vanool 957 [illegible]
Dough molding machine, F. Streich 957 [illegible]
Draft equalizer, J. Van Metre 957 [illegible]
Draft evener, G. I. Bristol 957 [illegible]
Drag, horse, W. C. Braun 957 [illegible]
Drift bolt puller, J. A. King 957 [illegible]
Drinking cup, collapsible, M. Shell 957,[illegible]
Drinking vessel, prophylactic, J. L. Sewell 957,[illegible]
Driving connection, flexible, S. M. Vauclain 957,370
Drying machine, Richardson & Neef 957,[illegible]
Dynamo driving, W. L. Thomson 957,[illegible]
Egg box, C. H. Kiefaber 957 [illegible]
Electric battery, F. A. Decker 957 [illegible]
Electric cable, R. F. Hall 957 [illegible]
Electric furnace, H. W. Hixon 957 [illegible]
Electric generator and motor, C. T. Hibbard 957 [illegible]
Electric heater, J. L. Logan 957 [illegible]
Electric machine, dynamo, J. R. Hoggewath 957 [illegible]
Electric machine, dynamo, W. D. Pomeroy 957,349
Electric meter, C. E. J. O'Keenan 957 [illegible]
Electric rosette, J. S. Crossley 957 [illegible]
Electric switch, H. M. Coffin, reissue 13,114
Electrical distribution system, W. A. Turbayne 957,[illegible]
Electrical distribution system, W. M. Winship 957,[illegible]
Electrical purposes, coil for, R. W. Jedrey 957 213
Electrically heated roller, G. H. Wade 957,[illegible]
Electricity meter, prepayment, H. Aron, 957,[illegible], 957 [illegible]
Elevator, W. Reubold 957,[illegible]
Elevator freight compartments, door attachment for, Snyder & Castle 957,[illegible]
Elevators, interlock mechanism for, J. S. Muckle 957 702
Engine primer, gas, L. R. Dalrymple 957,[illegible]
Engine starting and stopping mechanism, internal combustion, J. B. Pole 957,[illegible]
Ester from chaulmoogra oil, L. Taub 957 [illegible]
Excavator, H. F. Monek 957,[illegible]
Explosive, C. P. R. Claessen 957,[illegible]
Extension table, R. M. Miller 957 [illegible]
Extension table, K. Kral 957 611
Extension table, J. R. Weeks 957,[illegible]
Eyeglass mounting, T. Rapp 957 874
Fan, ventilating, R. A. Ilg 957 776
Fastener for gloves and other articles, L. W. Brown 957 [illegible]
Faucet, Bown & Smith 957,[illegible]
Faucet for drawing liquids, G. Wegman 957,534
Feed water by exhaust steam from steam engines, apparatus for heating, J. Kerfoot 957 [illegible]
Fence post, J. M. Campbel 957,[illegible]
Fence post, C. T. Howell 957 [illegible]
Fence wire clamp, T. M. Coffin 957 [illegible]
Figure, jointed, G. W. Ferguson 957 [illegible]
File cabinet, rotary, C. & W. Liebert 957 754
Files and rasps, machine for producing, G. Poissier 957 [illegible]
Filing cabinet, S. Klepfer 957 422
Filter bag, E. P. Dargis 957 191
Filter, vacuum, M. R. Miltner 957,[illegible]
Filtering apparatus, D. J. Kelly 957 [illegible]
Fire escape, M. F. Welch 957,[illegible]
Fish net, D. P. Gilstrap 957 [illegible]
Flagging, Hendricks & Burnap 957,[illegible]
Flat foot, weak foot, or fallen arch of the foot, device for the correction of, F. C. Schumacher 957 718
Fluid pressure motor, R. B. Holt 957,[illegible]
Fluid substances, decocting, A. G. Kalb, 957,[illegible], 957,[illegible]
Fly guard, P. Kreuscher 957,[illegible]
Folding machine, W. W. Christman 957,[illegible]
Folding machine, G. H. Petri 957,[illegible]
Frame. See Quilting frame
Furnace arch construction, C. Campbell 957,[illegible]
Furnace feeder, L. P. Nelander 957,[illegible]
Furniture, article of, S. A. Ward, Jr. 957,[illegible]
Furniture support, adjustable, G. E. Anderson 957,[illegible]
Gage, J. M. Leaver, Jr. 957 [illegible] to 957,[illegible]
[illegible] bag, J. A. Kalmrith 957,[illegible]
Game apparatus, A. W. Proctor 957,[illegible]

(Continued on page 428)

**THE ACCIDENT TO THE "ZEPPELIN."**

*(Concluded from page 416)*

"Zeppelin IV" did not involve the loss of any life. The "Republique" catastrophe, however, was tragic. On September 25th, 1909, the craft dropped from a height of about 200 meters to the earth, and its passengers, Capt. Marchal, Lieut Chauve, and the mechanicians, Vincennot and Reau, were killed immediately. The disaster was occasioned by the breaking of a propeller blade which flew off the shaft and pierced the gas bag.

The "Zeppelin II," whose untimely end has been described, was taken over by the army last year, and made a member of the German airship fleet. The vessel took part in last year's airship maneuvers at Cologne where it was stationed. In the spring of 1909 the vessel made a long journey from Lake Constance to Bitterfeld and return remaining uninterruptedly in the air 38 hours, until it collided with a pear tree at Goeppingen, and was partially damaged. The "Zeppelin II" had a volume of 15,000 cubic meters. Its length was 136 meters, and maximum diameter 13 meters. Its maximum absolute velocity was 12½ meters a second, or 28 miles an hour. Its carrying capacity, including passengers and supplies, was 8 800 pounds. It was provided with two cars. The two motors of the airship developed each 115 horse-power. The total weight of the "Zeppelin" was about 23,100 pounds. The balloon frame, rigging and keel, balloon fabric, gas bags, stabilizing planes and meters, weighed 13,200 pounds. The seventeen gas cells weighed about 2,500 pounds.

**Fire Control in the National Forests.**

*(Concluded from page 421)*

of way during the fire season, while the work of clearing the strips in a satisfactory manner, including the disposition of all refuse, is to be done by the railroads but under the supervision of the Forest Service.

One of the most potent reasons why this agreement is a good one is the fact that the courts have decided the right of the Department of Agriculture to collect damages from roads running through National Forests for fires which they cause, and this fact is a strong inducement for the roads to join with the department in the effort to keep fires down.

Another strong factor is the fact that the Northern Pacific, being a land grand road, owns considerable timber on the alternate sections along its line. The Great Northern, although it is not a land-grant road, also has property at stake in its buildings and the line itself whose operation may be seriously interfered with by forest conflagrations.

The value of heavy timber in mountainous regions as a deterrent to avalanches, landslides, and floods is also to be considered. From the standpoint of farsighted business policy a still broader argument is the relations of the forests to the general welfare of the regions whose traffic the roads handle. Timber which goes up in smoke pays no freight tolls and unchecked forest devastation means the enfeeblement of many industries dependent on wood and water.

**Practical Sterilization by Means of Ultra-Violet Rays.**

There seems to be little doubt according to The Lancet, that the germicidal action of the ultra-violet rays will shortly be made available for the purposes of practical sterilization. In what exact way the ultra violet rays act is not certain, but one view is that they produce ozone. Whatever the nature of the action may be, it seems clear that their application for the purpose of sterilizing articles intended for human consumption will eliminate the objection to the use of chemical antiseptics, the effect of which upon the human organism may be harmful. In an interesting paper which has reached us on the Sterilization of Water by Means of Quartz Lamps, by Dr Max von Recklinghausen, it is stated that work on a very large scale has lately been done in France on this subject, and has developed the entire system of sterilization of different liquids used for alimentary purposes, based on the effect of the ultra-violet rays created in Cooper Hewitt lamps made from transparent quartz. The chief work in this line has been done by Prof Henri in the Physiological Laboratory of the Sorbonne together with Dr André Helbronner, who co-operated with Dr Max von Recklinghausen with a view to developing an entire sterilizing system of the type described. The preliminary work was done by studying the action of the ultra violet rays on different types of microbes and the influence of the different wave lengths. Dr Roux of the Institut Pasteur in which a good many of the experiments were made presented to the Académie des Sciences some of the work done by the above cited scientists. Technically speaking the results so far have been the development of a small water sterilizer for hospital use whereby 132 gallons of sterile water are produced per hour from ordinary city water by means of one Cooper Hewitt lamp type "Silica," absorbing three amperes at 110 volts. Within a short time a very large sterilizing outfit based on somewhat similar ideas will be running which will sterilize 3 500 cubic feet of water per hour, this being large enough to treat the entire water supply of a town of about 10 000 inhabitants. The installation of the lamp it is stated, is a matter of no difficulty all that is necessary being to connect up to the terminals provided in the dome top of the apparatus and to make the adjustment necessary for the voltage of the particular circuit. In order that the supply of water delivered from the apparatus may be absolutely sterile or sterile to any required degree it is necessary that there should be means of dealing with the various water pressures met with in different districts. To accomplish this purpose the inlet pipe is fitted with an adjustable valve of special pattern which can be readily set, so that when full open the delivery from the apparatus does not exceed the quantity specified. This in the case of requirements being for absolutely sterile water, being 132 gallons per hour. The water enters the chamber formed by the outer cone with a swirling motion. At the top of this cone it overflows and finds an outlet at the bottom of the inner cone up which it rises and flows out at the discharge pipe. The swirling motion is maintained during the complete passage of the water through the apparatus in order that it may be thoroughly stirred up and all microbes presented to the action of the light the water coming under its influence on two distinct occasions. Draining cocks are provided on the apparatus to enable it to be thoroughly emptied should circumstances arise whereby it would not be used for a considerable time. Not only does this system provide in the case of the apparatus under discussion a continuous supply of sterile water available within five minutes, but the water or any other liquid that may be treated is unaffected as far as taste is concerned as it retains all natural gases and salts in solution. The work of Prof Henri, Dr Helbronner and Dr Recklinghausen has also been directed towards the complete sterilization of milk, and this they have also accomplished. The apparatus for this purpose is more difficult to build than that for the treatment of water. Water is very transparent to ultra-violet rays, milk however is practically opaque to these rays, and special precautions have to be taken so as to bring it thoroughly under their influence.

**A New Process for the Prevention of Coal-Dust Explosions.**

The production of coal dust in mines is due to the shattering of the coal when it is separated from the face of the work ing by the blast. The current of air

which passes through every coal mine from one ventilating shaft to another carries the dust into every part of the galleries, which may extend for several miles The distribution of the coal dust is further increased by the conveyance of coal in the mine cars, which usually move in a direction opposite to that of the air current, so that much dust is blown from them The dust settles in the corners and on the projections of the walls of the gallery, and especially on the floor and the tops of the timbers.

If the mixture of air and suspended coal dust comes into contact with a sufficiently hot flame a combustible gas is suddenly generated from the coal dust This gas, known as methane, or marsh gas is not explosive, except when it is mixed with air, in which condition it explodes with fearful violence The shock of the explosion scatters in the air much of the coal dust which has settled on the floor and elsewhere, and the heat produced by the explosion distills from this suspended coal dust a fresh quantity of methane which comes into contact with the flame In this manner the explosion is propagated from point to point, often throughout the entire mine

The possible means of preventing such extensive explosions of coal dust are confined to preventing the dust from rising in the air, and to disposing of the heat produced by the initial explosion so effectually that the further distillation of the coal dust and the formation of gas are prevented The heat produced by the initial explosion may be consumed in the evaporation of incombustible liquids, distributed through the workings The greater the quantity of such volatile liquid, and the greater the extent of surface exposed to the wave of explosion, the more rapid and effectual is the absorption of heat. The liquid used for this purpose at present is water It is necessary to wet or sprinkle every part of the mine in which coal dust exists This precaution is enforced by law in Germany and Austria but not elsewhere even in England, America, or France Most of the water applied to vertical surfaces quickly runs off, and the little that remains adhering to the surface evaporates in a few hours The effect persists a little longer on the floor of the gallery and other horizontal surfaces, but even the paste of coal dust and water that is formed on the floor soon becomes dry Hence the application of water must be frequently repeated Too frequent watering however, is injurious to the operation of the mine The water soaks into the porous rock and loosens it, causing danger of caving In very hot mines, the rapid evaporation of the water produces an exceedingly damp atmosphere, which is very injurious to the efficiency and health of the miners

The Kruskopf process for the prevention of coal dust explosions, which has recently been patented in Germany, employs instead of water a viscous paste, of such chemical constitution that it does not evaporate appreciably under the influence of the normal air current, but evaporates rapidly when exposed to the heat of a small explosion Owing to the adhesive character of the paste, it can be applied to all surfaces horizontal vertical and inclined and in about eight times the quantity which is possible in the case of water The thick paste, furthermore, does not soak into the rock and as it does not evaporate in ordinary conditions it does not increase the humidity of the atmosphere It has been proved by experiment that a coal dust explosion which in its nature is progressive, can be arrested by applying this mixture to the first hundred yards of the gallery this distance being sufficient to cause the explosion to die out owing to lack of explosive material In the actual conditions of mining the original ignition of coal dust takes place in almost every case, at the face of the

(Concluded on page 429)

(Continued from page 427)

(Continued on page 430.)

(*Concluded from page 428.*)

working, and the explosion is propagated thence through the gallery to the shaft. Hence, by applying this paste to a small region near each working, it is possible to confine the explosions to the workings themselves and to protect the rest of the mine, without the necessity of applying the same precaution through miles of galleries. This fact greatly reduces the expense and trouble involved in the method. Practical experiments in a Westphalian mine and in an experimental gallery have proved the correctness of the theory upon which this process is based. In the mine, the walls remained damp 3,000 hours after the application of the paste, but they dried up within six hours when water was used. The explosion of 75 grains of dynamite produces a sufficiently powerful flame to explode a mixture of coal dust and air when the walls of the gallery are dry, and for this reason the use of dynamite in coal mines is prohibited by law. The experiments prove that in a mine gallery protected by the Kruskopf process, more than five ounces of dynamite can be exploded in a mixture of coal gas and air without causing ignition. The experiment was repeated twelve times. After each blast, the quantity of coal dust in the mixture was increased by the addition of a fixed amount of dry dust, but the application of the paste or water was not renewed. In these conditions, when water was used, ignition took place after the third blast, but the first faint explosion occurred after the twelfth blast when the Kruskopf paste was employed. These conditions are very much more unfavorable than those which occur in the practical operation of coal mines.

### Colors of Foods.

Of the strong addiction many consumers have for the use of foodstuffs that are secretly and highly colored for the market, the London Lancet says:

"For some not quite clear reason there are many people who look upon the brown egg as necessarily a new laid one, and hence a fair demand for brown eggs has arisen, which is easily met not by the honest brown egg, but by the white egg which has been steeped in a dye which renders it visually indistinguishable from the real article. Again, when milk happens to be of a buff tinge, it is commonly held to be richer than white milk. Of course nothing can be easier than to satisfy this preference for a milk of a creamy shade. White-looking butter is disliked as looking too much like dripping. The remedy is simple, it is artificially colored. Vegetables must be bright green to make them look fresh, the consumers of them being quite willing to ignore the fact that copper does not make them fresh or wholesome. On the other hand, curiously enough, bread must be white.

"It is, of course, perfectly natural to take color as a criterion of the dietetic value or flavor of food, and the attractive or unattractive appearance of food may make all the difference as to whether that food is, or is not, assimilated properly. The deceit which is practiced by artificially coloring food may thus serve a useful purpose, so long as the coloring matter is harmless, but as a rule the proceeding is an immoral one. It does not follow that because food is unattractive its value as a food is nil, while every form of sophistication is open to commercial abuse. A correspondent last week submitted to us a brown-shelled egg which on opening displayed a gorgeous red coloring scattered chiefly through the white. On analysis the coloring proved to be an anilin dye. The dye had deposited a nice brown on the shell, but an excess had permeated its pores, and, meeting with the slightly acid contents, was changed to a port-wine color inside. Until the egg was opened, therefore, it appeared perfectly attractive, but on opening it the zest to eat it quickly disappeared."

## HALLEY AND HIS COMET

**The year 1910 is destined to be one of the most famous in astronomical history, simply because Halley's comet has returned after a lapse of seventy-five years. Why not learn all about this wonderful comet and about comets in general by reading the following articles?**

Scientific American No. 19, Vol. XCVIII. **Gas Phosphorescence and Meteor Trains.** An article in which the investigations of C. C. Trowbridge of Columbia University are described, showing that the after-glow produced from a vacuum tube resembles closely the effect produced in the sky by the passage of meteors.

Scientific American No. 6, Vol. XCIX. **The Mystery of Comets.** An article in which the famous comets of the last century are enumerated and described and modern cometary theories discussed.

Scientific American Supplement No. 1728. **Ancient and Popular Ideas About Comets.** Queer superstitions about the strangest of heavenly bodies.

Scientific American No. 7, Vol. CI. **Halley's Comet.** An interesting article by Dr. Alexander W. Roberts, in which the general history of Halley's famous comet is sketched with comments on its past appearances.

Scientific American Supplement No. 1705. **The Next Apparition (1910) of Halley's Comet.** An important article by H. C. Wilson, with a map giving the position of the comet relatively to the orbits of the planets from September 15, 1908, to July 13, 1910.

Scientific American Supplement No. 1632. **Halley's Comet.** An article by F. W. Henkel, F. R. A. S., which tells how Halley came to discover the comet which bears his name, and how mathematicians have plotted its orbit.

Scientific American Supplement No. 1770. **Edmund Halley.** A biography by J. E. Gore, M. R. I. A., of the man who dispelled cometary superstitions and popularized the law of gravitation.

Scientific American Supplement No. 1773. **Light Pressure and Comets' Tails.** An explanation of the vagaries of a comet's tail, by Arthur Stanley Eddington, F. R. A. S.

Scientific American Supplement Nos. 1788 and 1789. **Halley's Comet.** By George F. Chambers, F. R. A. S. The most thorough article which has thus far appeared on Halley and Halley's comet.

Scientific American No. 13, Volume CII. **Condensed Facts About Halley's Comet.** By H. W. Griggs. A few facts presented in condensed form for those who wish to follow the course of Halley's comet in the heavens. Maps showing the apparent path of Halley's comet through the heavens and the relation of the orbits of Halley's comet and the planets.

Scientific American No. 16, Volume CII. **Halley's Comet at its Brightest.** By Professor Henry Norris Russell. A simply worded astronomical article telling how Halley's comet was discovered on its present return, when it will appear at its brightest, where to look for it, what it is composed of, etc.

Scientific American No. 18, Volume CII. **How to Make a Model of the Orbit of Halley's Comet, Showing its Relative Position to the Earth's Orbit.** Designed by James K. Lynch. By means of this model many of the phenomena of Halley's comet can be explained.

Scientific American Supplement No. 1772. **Photographing Comets.** By R. E. Barnard, of Yerkes Observatory. A practical article on how to photograph Halley's comet.

Scientific American Supplement No. 1778. **Halley's Comet.** An article in which the suggested observations proposed by the Astronomical and Physical Society of America are given, so far as photography and spectroscopic observations are concerned.

Scientific American Supplement No. 1782. **Halley's Cometary Studies.** Halley's own account of his investigations on orbits.

Scientific American Supplement No. 1785. **Halley's Comet as Seen from the Earth.** A table prepared by the distinguished Greenwich astronomer, P. H. Cowell, giving the ecliptic co-ordinates of Halley's comet to two decimal places at intervals of four days through an arc extending from one end to the other of the latus rectum of its orbit. The figures apply approximately to any return.

Scientific American No. 10, Vol. CII. **Could the Earth Collide with a Comet?** An examination of past comet scares and the general possibility of collision of a comet with the earth.

First section of subways to be undertaken.

Chicago proposes gradually to place all tracks, surface and elevated, that enter the business zone, below street level. The above view shows a station on the new Wabash Avenue four-track subway. The trolley cars are to the right, the elevated express cars use the left-hand track. The lowest tunnel is the present 60-mile freight subway.

HOW CHICAGO IS SOLVING ITS RAPID TRANSIT PROBLEM —[See page 439.]

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## OUR NATIONAL GOOD ROADS LABORATORY

AMONG the less known, but by no means less important, sections of the broad field of activity covered by the Department of Agriculture, is that which comes under the Office of Public Roads. Although this office has no administrative duties and exercises no control over the roads of the United States—except of course, those that are located on government reservations—it is doing most important work of a scientific and educational character.

The movement for Federal assistance in the promotion of good roads dates back to the year 1893, when a modest appropriation of $10,000 was made, to enable the Secretary of Agriculture to inaugurate the work. To date a sum of nearly half a million dollars has been appropriated, and if this year's estimate be included the total reaches about six hundred thousand dollars.

A full account of the growth of this movement is presented on another page of this issue, and it gives us much pleasure to draw particular attention to that branch of the Office of Public Roads which is known as the Division of Tests. We make this special reference on account of the high character of its organization and work, and because one of our recent editorials would give the impression that no such division exists. As a matter of fact this laboratory, as we are informed by Director A. W. Page, is not only equipped with the best and most improved apparatus used in European laboratories, but has developed a number of additional tests, such as those for toughness and cementing value. Routine tests are made on road building materials free of charge for any citizen of the United States, and a large amount of experimental and research work is being carried on. Indeed it is justifiable to state that the laboratory of the Office of Public Roads is the most completely equipped road material laboratory in the world, and that the number of samples tested yearly is far greater than in any similar institution. As a matter of fact, during the present year about three hundred typical samples of the road building rocks of England, Scotland and Wales were tested by special request in addition to the regular routine work.

## ARBITRATION VERSUS SELF REDRESS.

AS surely as the duel has given place, among individuals, to the court of justice, will the awful arbitrament of war give way to the international tribunal; also as a corollary to this it may be written down that as the court of justice has back of it for the enforcement of its decrees the punitive machinery of the government, so will the international court be backed by some form of international police, composed of limited naval and military forces, in which each of the signatories to the international court will be represented.

One of the brightest auguries of the dawn of a world wide peace is to be found in the fact that it has become the fashion, during the past year or two, to speak of armies and navies as means for the preservation of peace. When the leaders of the world, be they presidents, kings or emperors, declare that every increase in the armed strength of their respective countries is undertaken for the express purpose of preserving peace, the statement is generally accepted as sincere. Although the advocates of peace by arbitration deplore the enormous investment of treasure, time, and labor involved in the maintenance of the vast military organizations of the civilized world, they are beginning to believe that the advocates of peace by war are as anxious as they themselves that the world's peace be permanently preserved.

The establishment of the noble principle of international arbitration will be, after all, merely a repetition in the international world of a process of evolution from barbarism to civilization, which has long ago taken place in the individual national world. Far back in the beginnings of human history, the principle of self redress was paramount. If wrong or fancied wrong was done, the injured party encompassed the death of his enemy by such ready means as might be at hand. Gradually, with the growth of intelligence, it was realized, not only that the injured party was but a poor judge of his own cause, but that the principle of self redress was subversive of the peace and happiness of the community. It was realized, also, that the man whose brain was clouded with the smoke of furious passion, was not so well qualified a judge as some third and disinterested party, who could look upon the case in dispute with an impartial eye, and so, gradually but surely, the principle of arbitration took shape and became the stable rock on which our wonderful modern system of national jurisprudence has been erected.

We have before us a lucid review of the growth of the principle of national arbitration in a pamphlet published by the Maryland Peace Society and written by James Brown Scott, lecturer on international law in the George Washington and Johns Hopkins universities. He refers to the three stages which were shown in the development of the celebrated Roman judicial system, which were as follows: (1) The private litigant submitted his controversy to an arbiter of his own choice for decision according to the conscience of a good and impartial man; (2) the magistrate or judge chosen from an official list or panel is preferred to a citizen arbitrator; (3) the administration of justice is regarded as the duty and therefore the right of the State, and a judicial system is prepared for and imposed upon the citizen.

The author of the paper sees the same unconscious development taking place in the gradual growth of arbitration between states. In early times they would choose as arbiter the Pope; in modern times, some foreign sovereign. The lack of continuity of decision in this system, which dealt with the individual case, led up to the second stage, dating from the first conference, which involved the appointment by international action of a panel of judges, from which judges forming the temporary tribunal are chosen. "We stand," says the writer, "upon the very threshold of the third and final development, when nations as a whole determine that international justice is the province of the international community, and constitute a court of international justice to which litigant states may resort in conflicts of importance." To-day much has been done. The organization, jurisdiction and procedure of this international tribunal have been determined. Now, we merely await the appointment of judges to establish a world wide court, in which the nations may obtain justice as easily and readily as private suitors in national courts of justice.

The author of this paper does not go into the question of the enforcement of the findings of international arbitration. It is our belief that an international court should be backed by an army composed of drafts from the various armies of the world, previous to their disarmament, limited in numbers and existing solely for the enforcement of its decrees.

## SIR WILLIAM HUGGINS AND HIS WORK

WITH the death of Sir William Huggins there passed away an astronomer whose pioneer work in the field of astro-physics has earned for him an enduring place in the history of science. It was largely due to Sir William's genius that the spectroscope became an instrument of astronomical investigation hardly less important than the telescope. His work was done so many years ago, and its results have been so far-reaching, that it is easy enough to value it at its true worth.

Huggins began his studies shortly after Kirchoff applied the terrestrial science of spectrum analysis to the study of the sun. Partly as a result of Huggins's efforts astronomers have been enable to observe the solar prominences at any time, without waiting for an eclipse, for the principle of spectroscopic visibility of prominence lines at the edge of an uneclipsed sun was quite explicitly stated by him in February, 1868. He even devised various instruments for bringing the prominences into actual view. His use of the "open slit" on February 13th, 1869, may be said to have begun the modern study of solar prominences. Before the days of the "open slit," prominences had been examined only in sections.

The first tangible results in the estimation of movements of approach and recession between the earth and the stars, by means of Doppler's principle, were communicated by Sir William Huggins to the Royal Society on April 23rd, 1868. Application of this method to the stars is encompassed with difficulties; for it needs a powerful dispersive spectroscope to show a minute line of displacement, and powerful dispersion involves a strictly proportionate enfeeblement of light. Selecting the brightest star in the heavens as the most promising subject of experiment, Huggins considered the F line in the spectrum of Sirius to be just so much displaced toward the red as to indicate recession at the rate of 29 miles a second. The inquiry was resumed by Huggins with improved apparatus in the following year, when the velocities of thirty stars were approximately determined. The scope of Sir William Huggins's achievement was not, however, to detect the motion in the line of sight so much as to establish the method of procuring data. His success has been of incalculable value, so much so, that the spectroscopic investigations of stellar movements may confidently be expected to play a leading part in the unraveling of the vast and complex relations which even now we dimly detect among the stars.

The first successful application of the spectroscope to comets was made by Donati in 1864. Comets had previously been considered to shine mainly, if not wholly, by reflected sunlight. They were now perceived to be self-luminous and to be formed, to a large extent, of glowing gas. The next step was to determine the nature of this gas, a problem first attacked by Sir William Huggins in 1868. Winnecke's comet (comet II, 1868) was the subject of his experiment. He first revealed the typical hydro-carbon spectrum with which we are now familiar. Tebbutt's comet (comet III, 1881) was the first comet of which the spectrum was photographically recorded, a feat in which Huggins was completely successful. That achievement threw open to investigation a part of the cometary spectrum invisible to the eye, so as to afford an additional test of cometary constitution.

In the field of stellar spectroscopy Huggins's work is assuredly monumental. Almost simultaneously, in 1862, this novel line of investigation was entered upon by Huggins in London, by Father Secchi in Rome, and by Lewis M. Rutherfurd in New York. Hence Huggins may well be considered as one of the fathers of stellar spectroscopy. When he brought to a successful culmination his early experiments in spectroscopic photography, we really began to learn something of the composition of the fixed stars. On December 18th, 1879, he was able to communicate to the Royal Society results answering to his expectations.

The dry-plate process, with which such wonderful results have been obtained in astronomical photography, appears to have been first made available by Sir William Huggins in photographing the spectrum of Vega in 1866. That work laid the foundation for the brilliant application of photography to astronomy by Common, Draper, Janssen, Rutherfurd, and later astronomers.

A fairly complete preliminary answer to the question, "What are the stars made of?" was given by Sir William Huggins in 1864. By laboriously comparing stellar dark lines and the bright rays emitted by terrestrial substances he sought to verify his conclusions regardless of cost in time and trouble. Although he himself averred that the full investigation of a single star spectrum would be the work of years, he was able to furnish however detailed and accurate drawings of the spectra of Betelgeux and Aldebaran.

Before Huggins applied the spectroscope to the study of nebulæ, it was felt that these mysterious, filmy objects of light would forever thwart the astronomer. Each new and more powerful telescope that made its appearance had resolved into clusters stars which previously had appeared to the naked eye as single orbs. It was felt that those filmy stars which had resisted all attempts at telescopic resolution might be similar clusters, for which reason some doubt was cast upon Herschel's theory that they were masses of "shining fluid."

On August 29th, 1864, Sir William Huggins sifted through his prisms the rays of a bright planetary nebulæ in Draco. To his infinite surprise, they proved to be of one color mainly and thereby proclaimed their gaseous nature. Thus Herschel's conjecture of a "shining fluid" diffused at large throughout the cosmos was unexpectedly verified. By 1868 Huggins had separately examined the spectra of about seventy nebulæ, of which one-third displayed gaseous characteristics. All of these gave the green ray fundamental to the nebular spectrum and emanating from an unknown form of matter named by Huggins "nebulum." A successful beginning in nebular spectrography was made by Sir William Huggins on March 7th, 1882. Five lines in all stamped themselves upon a plate, exposed to the rays of the nebula in Orion. Thus was photography definitely made the scribe of the nebulæ.

The effect of Huggins's work has been to remove the astronomer from the eye-piece of the telescope, to substitute for the retina the more sensitive photographic plate, and to teach the astronomer the immeasurable value of the spectroscope in analyzing the composition of stars which in the telescope appear as mere points of light pricked in a sable canopy. Huggins introduced physical methods into astronomy and transformed the observatory into a laboratory.

## AERONAUTICS.

On May 18th, M. [illegible] flew from Mourmelon to Chalons, France, a distance of about 30 miles across country. The flight was made in a biplane at a claimed speed of 46½ miles an hour.

Daniel Kinet, a Belgian, flew 2 hours and 51 minutes with a passenger in France on the 15th instant. This flight was also made in a biplane and constitutes a new world's record.

Mr. Clifford B. Harmon has been making some excellent flights of nearly a half hour's duration at Mineola, L. I., in the Farman biplane which he purchased from Paulhan. On the 31st he gained the pilot-aviator license of the Aero Club of America by making a [illegible]atic flight. He is the first amateur sportsman in America to take up aviation, and is doing a great deal for the cause.

Mr. Moore, of Washington, D. C., who has been Mr. Emile Berliner's assistant for some time past, has constructed a very light monoplane, fitted with a 25-horse-power revolving-cylinder motor. The machine and motor complete weigh but 260 pounds. The motor is placed above and between the wings at the front end of the machine. The cylinders revolve in a horizontal plane, and drive the propeller through bevel gears. Mr. Moore has gotten off the ground a number of times with his monoplane and made several successful short flights.

On May 18th, the day when the tail of Halley's comet was expected to sweep over the earth, Prof. A. Lawrence Rotch sent up a series of sounding balloons from his Blue Hill Observatory These balloons were equipped with meteorographs and with apparatus for obtaining samples of the air at high altitudes. Prof. Rotch's observations were made simultaneously with those of thirty other experiment stations scattered throughout Europe. Some members of the U S Geological Survey also attempted to catch particles of cometary dust at the Carnegie Observatory on Mount Wilson, California, by placing on a high tower a plate coated with glycerine Several balloon parties were organized throughout the country to view the comet when it was nearest to us.

Another new monoplane that has flown successfully is that of Mr. Gardner Hubbard, which was built by Messrs. McCurdy and Baldwin at Baddeck, Canada This machine is a cross between the Blériot and Antionette types. It has 260 square feet of supporting surface, the overall length being 34 feet and the spread of the wings 30 feet 2 inches It weighs complete about 1,000 pounds without the aviator, a 40-horse-power, six-cylinder water-cooled motor of 320 pounds weight furnishing the motive power The propeller is driven by sprockets and chain, with a gear reduction of three to five. On April 5th, nine flights were made above the ice on Lake Bras d'Or, by Mr. Hubbard, who had never flown before. The monoplane reached an elevation of about ten feet, and flew several hundred feet each time

In a recent aeronautic note we mentioned an aeroplane flight of five minutes duration with four passengers. As a matter of fact M Roger Sommer took but three passengers with him on his record breaking flight of April 20th. These were Mlle Dutrieux (45 kilogrammes, 99 pounds) and MM Colombo (60 kilogrammes, 132 pounds) and Frey (58 kilogrammes, 128 pounds) Sommer himself weighs 151 pounds. The total live load was 510 pounds, and the weight of the biplane complete was 550 pounds, making a total weight of 1,060 pounds that the 50-horse-power Gnome motor raised in the air in 90 seconds. The weight-lifting efficiency of Sommer's machine is therefore 92 per cent. The previous record of this kind was made by Henry Farman with a similar machine when he covered 10 kilometers in 10½ minutes with two passengers weighing 110 kilogrammes plus 30 kilogrammes of ballast.

On the 9th instant Messrs. A. H. Forbes and J C. Yates made an ascension at Quincy Ill, in the former's new balloon "Viking," one of the largest and most up-to-date aerostats thus far constructed. The aeronauts hoped to make new distance and endurance records, but in this they were disappointed They claim, however, that their balloon reached a height of 20,000 feet nearly 24 hours after they ascended. Because of the great height attained, a considerable amount of gas was lost, and when the balloon descended it was in a flabby condition. As a result of this the concentrating ring settled and pulled the rip cord (which was attached to it), ripping open the balloon when it was [illegible] feet above ground. It dropped suddenly without any retardation, as the envelope failed to form a parachute. The basket struck the ground squarely and the aeronauts were rendered unconscious. Fortunately they escaped without serious injuries owing to the cushioning effect of a pneumatic mattress which they had in the car.

## ELECTRICITY.

By using a stethoscope and a sensitive telephone relay, the heart beats of a patient in London were transmitted to the home of John Milne, the noted seismologist, on the Isle of Wight. The heart throbs were heard by four physicians over an ordinary telephone, and so clear, was the transmission that it was possible to diagnose the heart troubles It is expected that this use of the stethoscope with a telephone relay will enable physicians to keep in better touch with their patients.

An electrical thermometer which is very sensitive to slight fluctuations of temperature, has recently been put out by a German company for medical use, to determine the degrees of fever It consists of a coil of platinum wire inclosed in a quartz glass tube, through which a current is passed from a four-volt storage battery The tube is placed in the armpit of the patient, and a milli voltmeter indicates variations in the resistance of the coil, due to the heat of the body The milli-voltmeter traces a temperature curve on a band of paper, and in this way it is possible to study the action of drugs on the patient.

According to a recent press report, steamships of the French trans-Atlantic line are using the apparatus invented by Signors Bellini and Tosi of the Italian navy, by which wireless messages may be transmitted in and received from, any desired direction The particular advantage of this apparatus on shipboard is the fact that it enables the operator to determine from what direction a signal is coming, and the course of the vessel can be governed accordingly. Recently the "Provence" crossed the Atlantic, equipped with this apparatus, and was able to determine the positions of various vessels passing in the vicinity The danger of collision was thus entirely obviated

An interesting paper on insulating materials for wireless telegraphy was read recently before a meeting of the Wireless Institute in this city by Mr Stanley M. Hills. He pointed out that rubber is not permanent, but apt to deteriorate, that marble is hydroscopic and not to be relied upon because of its irregular composition, that porcelain is apt to contain hidden defects, and that glass, while the defects it contains may be detected visually and thus avoided, is extremely fragile He spoke of mica and of wood as good insulators if kept dry, and dry oil is a good insulator for the reason that it is liquid and "self-healing" Dry air makes an excellent insulator, and for high voltages, compressed air may be used

The advantages of an electrical shovel over a steam shovel have recently been portrayed, showing that wherever electricity is available at moderate rates, the electric shovel is much to be preferred One of the great objections to the steam shovel is the fact that the expenses of a fireman must be paid, and the fuel, as well as the water, have frequently to be carted for a very long distance. Steam must be kept up continuously, despite all delays in operating the shovel, while for the electric shovel the same arguments apply as are made in behalf of electric drive in machine shops, namely, that when the shovel is idle there is no consumption of power, yet the power is ready for instant use whenever it is needed

An interesting discussion by Dr Charles P Steinmetz on the magnetic properties of materials was published in a recent number of the Electrical World It was stated some years ago that magnetic alloys could be made by combining non-magnetic materials Dr Steinmetz points to the fact that in all the Heusler alloys manganese is used, and that this is slightly ferro-magnetic One of the simplest of these alloys consists in combining one part of manganese with three parts of antimony, the mixture being made by powdering the metals and then heating them in a test tube. The result is a black powder which is strongly magnetic, Dr Steinmetz states that no magnetic alloy has been found which does not contain some of the ferro-magnetic group—iron, cobalt, nickel, manganese, and chromium

Now that air craft have been entered as war vessels, inventors are beginning to cast about for some effective means of destroying them. Recently an aerial torpedo has been invented, which, by means of a Hertzian wave controlling system, may be directed from a distance without carrying any operator. This torpedo was exhibited at the London Hippodrome, where the inventor caused it to travel out over the audience, steering it wherever he chose by pressing buttons on a switchboard on the stage The torpedo is provided with two screws, which may be operated independently to steer the ship laterally, while a horizontal rudder serves to steer the vessel vertically. The device may also be equipped with explosives, to be dropped on the enemy when the torpedo has been maneuvered to the right position This was demonstrated at the Hippodrome by releasing flowers on the audience.

## SCIENCE.

Edward B. Garriott, chief forecaster of the United States Weather Bureau, died recently at Washington at the age of 57 He had been connected with the Weather Bureau practically since its establishment, which means for forty years

After thirty months' cruising in Philippine waters, the Fish and Game Commission's steamer "Albatross," Commander C M McCormick, United States Navy, entered the Golden Gate, San Francisco and dropped anchor The "Albatross" has been engaged in a thorough examination of the fish in Philippine waters

When one solid body glides over the surface of an other, the coefficient of friction diminishes as the velocity increases and nearly vanishes when the velocity attains a certain critical value This diminution of friction is due to the air which partially separates the two bodies at low relative velocities and separates them completely at the critical and all higher velocities.

Dr Douglas Mawson, who accompanied Sir Ernest Shackleton on his last Antarctic expedition, arrived recently in this country, bound for Sydney New South Wales, to resume his duties as lecturer on geology in Sydney University Dr Mawson reiterated the statements already made by Sir Ernest Shackleton that there is an immense stream of coal within 300 miles from the South Pole

An interesting method for measuring the transparency of developed photographic plates has been devised by Dr L. H Friedburg A polarized light apparatus is employed An opaque plate not rotating the plane of polarization, when interposed between two parallel mounted tourmaline plates cut parallel to their optical axes, will reduce the angle of 90 deg between extreme brightness and maximum darkness by an amount proportional to the density of the silver deposit.

The emission spectra produced by certain elements heated in quartz tubes to 2 500 deg F have recently been studied It is found that in these circumstances sulphur produces a blue light and a nearly continuous spectrum Selenium gives a pale yellow light with bands, which are generally well defined, but become uncertain toward the red end Tellurium emits a green light and its spectrum contains numerous bands which are also hazy toward the red end Phosphorus and arsenic give a white light and continuous spectra, while antimony produces a nearly continuous spectrum, crossed by very ill-defined bands

The distinguished German chemist Ostwald has taken out a German patent for the improvement of drawing inks and water colors He has found that by the addition of small quantities (from 1 100 to 1 1,000) of volatile organic compounds of the aliphatic series, which are soluble in water, at least to a small extent and contain not less than four atoms of carbon inks, drawing inks and other water colors are rendered capable of readily marking such surfaces as parchment ivory, waxed paper etc In the case of neutral liquids, an alcohol, ester, or other neutral substance is used, while to acid inks, free fatty acids, such as valeric or caproic acid may be added

How bright is the sun? No two authorities agree Another estimate has recently been made by C Nordmann The effective temperature determined with his pyrometer was found to be about 5 320 deg absolute Now, the brightness of an incandescent body emitting white light varies sensibly as a function of the temperature, and this law has been verified by comparison with numerous terrestrial light sources. Taking into consideration the absorption of the solar atmosphere, the effective temperature of the photosphere is probably about 6,450 deg absolute The corresponding brightness of the mean effective layer is then about 319 000 decimal candles per square centimeter The solar surface is thus considered to behave very like a black body, and to have an emissive power of nearly unity

Ducelliez has made a study of the chemical character of various alloys of cobalt with tin, antimony bismuth, lead, and copper, by measuring the difference of potential between each alloy and each of its constituents, when immersed in a solution of cobalt sulphate The results are expressed in graphical form The curve of the cobalt-tin alloys shows a distinct inflection at the percentage of 66 76 of tin, which corresponds to the compound CoSn The cobalt-antimony curve indicates the existence of two definite compounds, CoSb and $CoSb_2$. The cobalt bismuth alloys also show two distinct compounds The electromotive force produced by most of these alloys is very small The curves show that in the separation of the two metals by the process of solution, the cobalt remains undissolved in practically pure condition, while the solution of bismuth contains about 5 per cent of cobalt. The behavior of the cobalt lead alloys is similar to that of the alloys of cobalt and bismuth.

# THE LATEST GIANT FREIGHT ENGINE

## FOR USE ON THE HEAVY GRADES OF THE DELAWARE & HUDSON RAILROAD

It takes but a glance at these photographs of the huge Delaware & Hudson freight engine recently turned out from the shops of the American Locomotive Company to realize to what Brobdingnagian proportions the freight engine has grown. The two men inside the 41 inch low pressure cylinders one of them comfortably seated, the stalwart mechanic standing erect in the 90 inch front end of the boiler with a foot and a half clearance between his head and the roof, tell their own story of dimensions. To this may be added the following particulars. There are, as usual in the articulated type, two engines on two trucks, the forward a low pressure with cylinders 41 inches diameter by 28 inches stroke, the after engine a high pressure with cylinders 26 inches diameter by 28 inches stroke. Each engine drives eight, coupled, 51-inch driving wheels which carry the whole weight, 445,000 pounds, of the engine. The tractive power working compound is 105,000 pounds, and the calculated horse-power under ordinary working is over 2,600.

The huge boiler, 90 inches diameter at its smallest ring, has a total heating surface of 6,6[illegible] square feet, and it supplies steam at 2[illegible]0 pounds pressure.

The tender carries 9,000 gallons of water and 14 tons of coal; its weight loaded is 16[illegible],800 pounds, and the engine and tender together weigh 611,800 pounds.

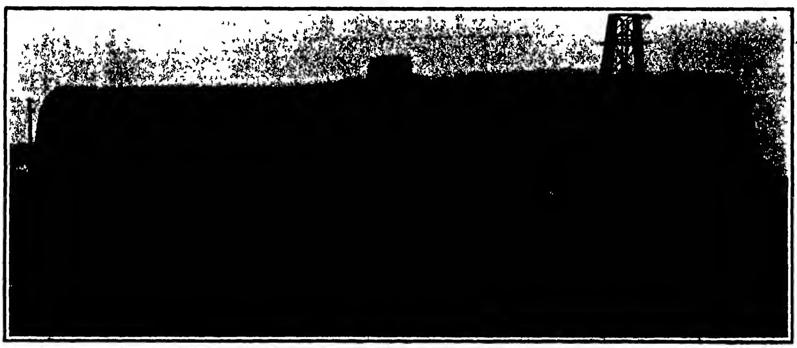
The engine can haul on the level at [illegible] miles per hour 100 fifty-ton cars, each of which loaded will weigh [illegible] tons. This will mean a load behind the tender of 7,2[illegible] tons, or a total load for the train of over 7,500 tons.

The company has built six of these engines for the Delaware & Hudson Company. They are designed for pusher service on the Wilkesbarre & Susquehanna division of that road, between Carbondale, Pa., and Oneonta, N. Y.—a distance of 95

(*Concluded on page 449.*)

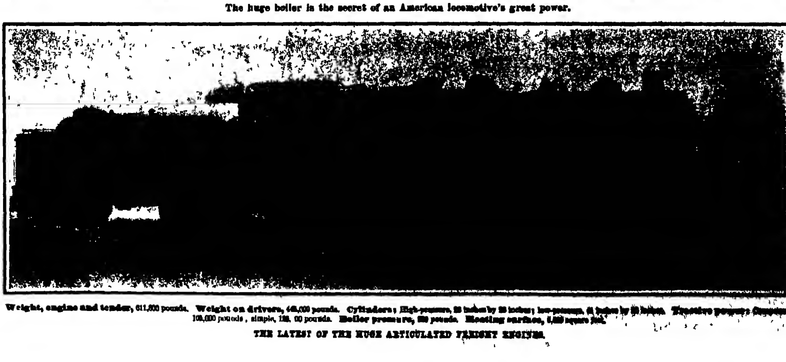
A man can be comfortably seated in each of the 41-inch low-pressure cylinders.

Front end of boiler is 7½ feet diameter.



Largest diameter, 96 inches. Length, 44 feet 10 inches. Weight with water, 80 tons. Firebox, 10 feet 6 inches by 9 feet 8 inches—would make a fair living room.

**The huge boiler is the secret of an American locomotive's great power.**



Weight, engine and tender, 611,800 pounds. Weight on drivers, 445,000 pounds. Cylinders: High-pressure, 26 inches by 28 inches; low-pressure, 41 inches by 28 inches. Tractive power: Compound, 105,000 pounds, simple, 12[illegible],000 pounds. Boiler pressure, [illegible] pounds. Heating surface, [illegible] square feet.

THE LATEST OF THE HUGE ARTICULATED FREIGHT ENGINES.

# Eiffel's Recent Experiments on the Resistance of the Air

BY JACQUES BOYER

Eiffel's first experiments on the resistance of the air, a problem which is now engaging the attention of many scientists because of its importance in aeronautics, were made in 1907-8 at the famous Eiffel Tower, which was constructed for the Paris Exposition of 1889. The surface on which the pressure of the air was to be studied was allowed to fall from the platform of the second story of the tower, in connection with a chronographic apparatus, which recorded the resistance opposed by the air at each instant. The surface was carried downward by a heavy and dense mass, offering little resistance to the air. This mass was placed above the surface, with which it was connected by springs, which were compressed more or less, according to the air resistance. The velocity of fall ranged from 60 to 130 feet per second. The apparatus was guided in its fall by a vertical cable, and was prevented from striking the ground by a progressive enlargement of this cable beginning at the height of about 70 feet from the ground. In this way the falling body was gradually brought to rest by the action of spring brakes. A tuning fork, making 100 vibrations per second, was attached to the surface. To one of the prongs of this tuning fork was attached a style, which as the fork vibrated, moved vertically over the surface of a vertical cylinder, which was covered with paper coated with lampblack, and was caused to revolve with a speed proportional to the velocity of fall. Hence the record takes the form of a fine sinusoid, the median line or axis of which forms an irregular line around the cylinder. Each point of this axis corresponds to a certain position of the falling body. The number of undulations between this point and the beginning of the trace, gives the time; the ordinate of the point indicates the tension of the springs, and consequently the pressure of the air on the surface, at that instant; and the abscissa is proportional to the distance through which the body has fallen. Hence the trace gives the position and velocity of the body and the resistance opposed to its motion by the air at every instant. Eiffel experimented in this way with plane surfaces of various forms, square, oblong, circular, continuous, and cut or perforated, with groups of superposed plane surfaces, and even with spherical and conical surfaces. He arrived at the following conclusions. For velocities between 60 and 130 feet per second, the resistance of the air is very approximately proportional to the square of the velocity. The exponent of the velocity differs very slightly from 2 and appears to increase regularly with the velocity, passing through the value 2, at the velocity of 110 feet per second. The pressure per square inch was furthermore found to increase with the area of the surface.

The influence exerted by superposed surfaces on each other is very great. In some cases the resistance is smaller for a group of surfaces than for a single surface. For surfaces inclined to the direction of the wind, Eiffel formulated in 1908 the following law. For inclinations to the horizon varying between 0 and 30 degrees, the pressure is proportional to the angle, while for inclinations greater than 30 degrees, the resistance is constant.

In order to extend these observations (which have been fully described in the SCIENTIFIC AMERICAN) Eiffel constructed in 1909 an aerodynamic laboratory at the Champ de Mars, Paris, where he has subsequently conducted experiments with fixed surfaces, exposed to air currents produced by a blower of 50 kilowatts power. By this method he was able not only to obtain the resultant pressure, but to determine the distribution of pressure on both sides of the surface and the movement of the air in its vicinity.

Fig. 9.—The Eiffel aerodynamic balance placed above the experiment room.

In order to place the surface in conditions as nearly as possible identical with those produced by a natural wind or by movement in the open air, the air current must have so large a cross section that its exterior filaments will not be affected by the presence of the surface. The pressures experienced by the surface are measured by an aerodynamic balance, by which it is possible to determine the horizontal and vertical components, as well as the center of pressure, data which are very important in the construction of aeroplanes. The aerodynamic balance is shown in diagram in Figs. 1 and 2. The experimental surface is attached to the rod $C$, which is placed parallel to the air current. This rod is attached to a rigid T-shaped frame $DE$, which is capable of motion around a knife edge $A$. The action of the air current is opposed by an upward pull at $f$ produced by the weight $P$, in the balance above. When equilibrium is established the moment of the forces which tend to move the experimental surface and its support round the knife edge $A$, can be computed from the weight in the scale pan. Two weighings are made, when the air is at rest and when it is in motion at known velocity. The moment produced by the air current is the difference of the two results. The other end of the rod $E$ carries a second knife edge $B$, which is directed upward and which can be brought to bear against its seat by shortening the rod $H$, by means of the eccentric $G$. In this way the moment of the air pressure around $B$ can be measured. Thus it is possible to measure the moments of the pressure with respect to two points, furthermore, as the rod $C$ can be rotated about its axis, the elements of the resultant pressure upon an inclined surface can be determined by making four measurements, at azimuths differing by a right angle. The vertical part $D$ is a rod of cast steel, which is capable of slight motion in a sheath attached to the floor of the room above, on which the balance stands. This sheath which is very narrow and is beveled in front and behind, protects the vertical rod from the air current, without appreciably affecting the latter. The horizontal part $F$ is provided with a pair of knife edges at each end. The knife edges at the front or windward end $A$ are directed downward and backward, while those of the other end $B$ are directed upward and backward. The seats of these knife edges have projections, which prevent the knife edges from moving along the grooves in which they turn. By moving a lever, the knife edges in front can be lifted from their seats to protect them from wear, except during the actual experiment. The rod $H$, which connects the frame $E$ with the beam of the balance, touches these parts only by means of knife edges. In short all the moving parts of the apparatus turn on knife edges, and the friction is negligible. The T-shaped piece $DE$ weighs more than 100 pounds. This great weight is not an inconvenience but serves two useful purposes, by lessening and damping the secondary oscillations, due to small variations in the force of the air currents and by making the equilibrium of the balance stable in every relative position of the current and the surface. The entire apparatus is supported by a massive wooden platform, about 8 feet square, which rests on a double layer of sleepers, buried 10 feet below the floor of the room and lying parallel with the direction of the air current.

The current of air is drawn through a tube 6½ feet in diameter, and every precaution is taken to keep its strength uniform during the experiment. The air is drawn from a large closed room in which the surface

Fig. 6.—Experiment room of Eiffel's aerodynamic laboratory.

Fig. 7.—The inlet of the blower.

Fig. 8.—Arrangement of apparatus for measuring pressures at various points of the surface.

EIFFEL'S RECENT EXPERIMENTS ON THE RESISTANCE OF THE AIR.

is placed near the inlet of the blower, and not at its outlet, as is usually done The air which leaves a blower is subjected to irregular disturbances, which cannot be overcome sufficiently to produce uniform and constant velocity over the entire surface The pressure exerted upon the surface is transmitted to the balance in the room above, where the observer is stationed The air enters the experiment room through a cellular diaphragm in parallel filaments At the opposite end of the room is the mouth of the conduit which leads to the blower and which contains two iron-wire gratings of 2/5 inch mesh, placed about 40 inches apart which almost completely eliminate all irregularities of flow The air leaves the blower through a conduit which gradually enlarges and serves still further to assure regularity of flow Hence, the velocity and direction of the air current are uniform through out its whole section and, as the apparatus is entirely inclosed, it is not affected by the wind outside

The velocities of the air current are deduced from the readings of manometers, and the results have been verified in the following manner One of the surfaces exposed to the current was perforated with a large number of holes, in each of which was countersunk a screw, having at its center an orifice 1/50 inch in diameter By measuring with a small manometer the pressure produced behind each of these orifices, and integrating the result, the same resultant force that had been indicated by the balance was obtained

We cannot here relate in detail all the interesting results which Eiffel and his assistant Léon Rith have already obtained in this laboratory We will mention only a few of the more important conclusions

Eiffel has proved that the value of the horizontal component, or resistance to the advance of an aeroplane, increases continually with the inclination of the surface to the horizon, while the vertical component attains a maximum at an inclination of 15 degrees, and thereafter diminishes very rapidly, and vanishes at 90 degrees, i e, when the plane is vertical

The surfaces employed in these experiments had a plane of symmetry parallel to the wind In order to determine the directions of the air filaments in this plane, a short and very light wire, attached to the end of a thin rod, was placed at various points of the plane, and the position and direction of the wire were determined as accurately as possible In most cases it was found that especially near the front edge of the surface, the direction of the wire fluctuated rapidly between two fixed limits This fluctuation in the direction of the wire is due to the fact that at any instant the air flows according to a definite, but not very stable, system so that only a very small influence is required to pass from one system to another The various possible systems of flow could be approximately determined by careful observation and comparison of the directions of the wire

Fig 3 shows the directions of the air filaments near a square surface, the plane of which makes an angle of 40 degrees with the direction of the current Fig. 4 shows the directions of the stream lines near a surface inclined 80 degrees to the current. It will be observed that these lines are very variable and consequently very instable The same fact is shown when the surface is perpendicular to the current. Fig 5 shows the average direction of the air at various points in this case In the two regions inclosed by the dotted lines, the disturbance is so great that no mean direction of flow could be determined

In regard to the center of pressure, this coincides with the center of figures if the surface is horizontal, gradually moves forward as the inclination increases to 15 degrees, and thence recedes as the inclination is increased, and again attains the center of figure when the surface becomes perpendicular to the current. Finally, Eiffel indorses the almost universal preference of aviators for curved sustaining surfaces, and proves that, for a given resistance to forward movement, the curved surface always develops a greater lifting power than the plane surface, especially at small inclinations.

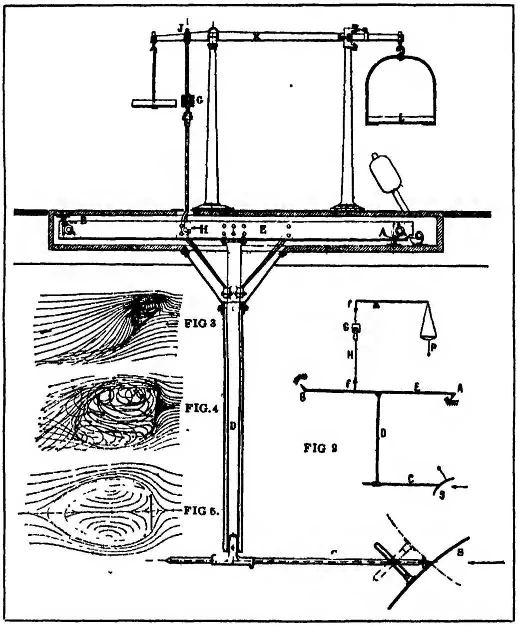


Fig 1 The Eiffel aerodynamic balance. Fig 2. Diagram of the balance. Fig. 3. Direction of stream lines near a square plate inclined 40° to the air current Fig 4 Stream lines near a square plate inclined 80° to the air current. Fig 5. Stream lines near a square plate perpendicular to the air current.

### The Transit of Halley's Comet.

The transit of Halley's comet and the expected immersion of the earth in the tail of that historic body have proven once more what may happen to the best-laid plans of mathematicians. The transit undoubtedly occurred, but whether or not the earth really encountered the tail seems to be a matter of considerable doubt. When the night of May 18th came, and the scientific world was all agog, the tail was so curved that the passage of the earth through it seemed only remotely possible On the morning of the 20th a broad band of light that stretched along the horizon for a distance varying from 120 to 160 degrees proclaimed indubitably that the earth was still untouched, and that contrary to expectations, the comet was still in the east Prof W W Campbell, of the Lick Observatory, saw the comet visibly in the eastern sky According to him, the tail was at least 140 degrees long and lagged far behind the radius vector Because of the angle of 18-odd degrees which separates the earth's orbit from that of the comet, the curvature of the tail, to which this extraordinary misadventure may probably be traced, probably prevented the earth from coming in contact with it.

All the scientific expeditions which have been sent out to various parts of the earth will probably come back with nothing to report. Some of these scientific parties must have proceeded to their destinations at considerable expense Thus Prof Birkeland, of the University of Christiania, went to Kaafjord, in the northern part of Norway, for the purpose of noting whatever electrical and magnetic effects might be attributed to the comet's tail, and particularly to observe the relation of the aurora borealis to the comet. He has his own theory that the particles of a comet's tail are so highly electrified that they may, in some way, affect the aurora borealis. The failure of his expedition, which it is almost safe to predict, still leaves that theory unproved.

Similarly unsuccessful must be all the elaborate preparations made by meteorologists, navigators and physicists. The more important meteorological stations of the world sent up sounding balloons at frequent intervals on the 18th and 19th of May, for the express purpose of bringing down from the upper strata of the atmosphere some record of unusual happenings which might safely be attributed to the influence of the comet. All this labor is now in vain. Similarly, it is very unlikely that the instructions sent forth by the United States Hydrographic Office to wireless operators, charging them to note any curious and unusual effects on their instruments, will prove barren.

The expedition which was sent to the Hawaiian Islands by the Astronomical and Astrophysical Society of America for the purpose of observing the transit cables a preliminary report of complete inability to note any transit whatever. This was more or less expected In 1882 a transit occurred which was fortunately observed by Mr Finlay at the Cape of Good Hope. The comet of 1882 was followed by him "continuously right into the boiling of the limb." No sooner had it touched it, than it vanished as if destroyed So sudden was the disappearance, that the comet was at first believed to have passed behind the sun As a matter of fact, the observers at the Cape had witnessed a genuine transit The experience of the observers at the Hawaiian Islands with Halley's comet seems to have been exactly similar On the whole, this apparent failure to observe the creeping of a black speck across the face of the sun may be deemed a confirmation of our present theories that the bulk of a comet is much too flimsy to be detected in the blinding glare of our central luminary

Although the passage of the earth through the tail of Halley's comet turned out to be an extraordinary disappointment, it is unfair to charge our mathematical astronomers with incompetence A comet's tail is so capricious, so fluctuating a structure, it changes with such startling rapidity, that the predictions of any astronomer with regard to its behavior must always be stated with some reserve.

The tail of Halley's comet has conducted itself in a most whimsical fashion In the middle of February, it was some fifteen million miles long. In April, it seemed to have vanished entirely. Then it grew again, until finally it attained a length that has been variously placed at twenty to forty million miles. It seems to have split longitudinally into three more or less well defined parts. When we consider that Morehouse's comet of 1908 (comet C, 1908) exhibited some extraordinary changes; that it repeatedly formed tails, which were discarded to drift out bodily into space, until they finally melted away; that in several cases tails were twisted or corkscrew shaped, as if they had gone out in a more or less spiral form; that areas of material connected with the tail would become visible at some distance from the head, where apparently no supply had reached it from the nucleus; that several times the matter of the tail was accelerated, perpendicularly to its length; and that at one time the entire tail was thrown forward and violently curved perpendicularly to the radius vector in the general direction of the tail's sweep through space (a peculiarity opposed to the laws of gravitation), it is evident that a comet presents important problems for the future astronomer to solve. It is no wonder that Halley's comet should have disappointed us.

## MEASURING AEROPLANE HEIGHTS.

To the Editor of the SCIENTIFIC AMERICAN

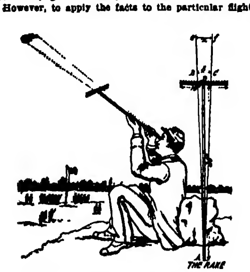
Replying to your communication of recent date, requesting me to forward a drawing of an apparatus which some French journal has stated I have for ascertaining the height of an aeroplane in flight, I beg leave to say that there is some inaccuracy in the statement as quoted.

Primarily, the apparatus used were merely a roughly-made "range rake," such as has been in use for some time in the Coast Artillery Corps for computing the "overs and shorts" that occur during their big-gun practice. Secondarily, in so far as accuracy is concerned, it cannot by any imagining be considered as accurate as a triangulation method employing two transits with a long connecting base line.

The "range rake" is simply a wand about three feet in length, having at one end a set of fine sawteeth placed at right angles to the wand on a metal strip several inches in length. Measurements are taken between teeth to the right and left of the middle tooth.

The principle on which this depends is that of similar triangles, the same being illustrated by the accompanying diagram. From this diagram and description it can readily be seen that the short base line precludes any great accuracy in the computations.

However, to apply the facts to the particular flight



MEASURING ALTITUDE OF AEROPLANE WITH A RANGE RAKE.

B C : A D :: e f : A x; ef=width of aeroplane, B C apparent width measured on the rake.

which was referred to in the French journal, I am of opinion, personally, that Paulhan actually attained an elevation of approximately forty-six hundred feet, for the following reasons.

1 The official figures were taken by two transits set one thousand feet apart. The solution of the obtained triangles gave him an altitude of 4,165 feet. The method and computations of the triangles were undoubtedly correct. The error, if any, was due to the fact that he attained his maximum height when crossing the line joining the transits. This so appeared to me. At that time, owing to the acuteness of the angle of elevation, it was impossible for either transit to take a reading, both being interfered with by the horizontal bases of the instruments. The maximum height as taken by these transits was when Paulhan was distant from the base line approximately one mile.

2 Paulhan had with him an aneroid barometer, corrected but not sealed. He stated that this registered a maximum of 4,600 feet (after being reduced from meters).

3 The maximum height as taken by Capt. Samuel Bottoms, Coast Artillery Corps, U. S. A., and myself with a "range rake" was 5,287 feet.

From all of the above I am of the opinion given above, viz., that Louis Paulhan actually attained a height of approximately four thousand six hundred feet at the Los Angeles meet, but am also of opinion that the official figure of 4,165 feet was the only one which could have been accepted under the circumstances.

PAUL W. BECK,
First Lieutenant Signal Corps, United States Army.
Presidio of San Francisco, Cal.

---

The output of the Clyde shipbuilding yards during April totaled 59 vessels and 60,000 tons, which is the largest recorded since July, 1907, when the output totaled 67,000 tons. The aggregate for the four months amounts to 154,000 tons, as compared with 99,000 tons in the corresponding period of last year. The total includes a battleship. A fair amount of new work has been booked during the month, and prospects are [illegible]

## HOW CHICAGO IS SOLVING ITS RAPID TRANSIT PROBLEM.

BY D. E. STEVENS.

The city of Chicago has been hard at work rehabilitating its surface street-car systems, and completing plans for the new subway lines. The engineers of the city have estimated how many passengers enter and leave Chicago's six square miles of business area every twenty-four hours, and the results prove that the present lines are hopelessly overworked. During two normal business days of the past year it was found that on all of the lines running into the down town district bounded by Chicago Avenue on the north, by Twelfth Street on the south, on the west by Halsted Street, and on the east by Lake Michigan, an area of about six square miles, every seventh passenger was without a seat. When it is remembered that the service cannot be improved much along present lines, it is clearly seen that a subway is imperative. At a conservative estimate, the next generation will see a demand for train facilities from the central district of the city equal to all facilities now available from the central part of New York city, with all its ferries, tunnels, subways, bridge and surface lines. To meet this need, the engineers have planned a system which it is believed will adequately meet this great demand for cars during the rush hours.

The complete system will be bounded on the north by Chicago Avenue, on the south by Twenty-second Street, on the west by Halsted Street, and on the east by Wabash Avenue. Four terminal stations will be built immediately at the boundaries of this subway zone, one at Chicago Avenue and North Franklin Street, one at Dearborn and Twenty-second Streets, another at Van Buren and Halsted Streets, and the fourth at Randolph and Halsted Streets. The new underground will begin where the four elevated lines now enter the district, and all surface cars from the respective quarters of the city will also converge at these four terminal stations, where all surface and elevated cars from the resident districts will become subway cars, and will remain under the surface until they again pass out of the district.

As shown in the front page plan, a four-track route will run close to the surface of Wabash Avenue from Chicago Avenue to Twenty-second Street. This route will carry all through cars from the South and North Sides, two tracks being exclusively for surface cars and two for elevated trains. After passing to the opposite limit of the district, the trains from each direction will turn about and will return to their respective starting points by the same route.

From the West Side of the city two tubes will run in beneath Randolph and Washington Streets as shown in the accompanying plan, and will turn southward on State Street, and then return to the West Side under Adams Street and Jackson Boulevard. After coming out into daylight at the Halsted Street terminal, these cars will also scatter to all points on the west side of the river.

To complete this first stage of plan one will cost about forty millions of dollars. Its capacity will be fifty per cent greater than that of all the traction lines now operating within the district. With the aid of surface cars to make short hauls within the business district, this plan will serve the needs of the city for many years.

An additional expenditure of forty millions will then build the second stage of this plan, when other busy streets will cover branches of the system. In this stage of the development will be found both loops and through routes for all parts of Chicago. Yet where the various tunnels cross one another there will be no grade crossings: one tube will dip in its course so as to pass completely under the other line. This will eliminate all danger of underground collisions.

A further expenditure of thirty-two million dollars will serve to complete the system, when every street within the subway zone will have beneath it a branch of the subway. Two, three, and four-track subway lines will honeycomb the whole area, and the entire district will be served by the most elaborate, yet the most efficient, subway system in the world. This plan, in its completed form, will cost about one hundred and twelve millions of dollars, and will serve the needs of the city at its present rate of growth until 1950. Improved methods of transportation will probably cause the business district to expand, and the subway will be built accordingly. It may ultimately be possible to remove every yard of rail and every car from the surface of down-town streets.

On our front page is shown a cross-section of one of the future stations on Wabash Avenue. As seen in this picture, the tracks lie close to the street surface. Because of the danger to certain building foundations, a low-level subway is impracticable, and the cost would be prohibitive. As the entire subway is to lie in the soft blue clay that underlies the business district, a special type of construction will be needed. The concrete core of the subway walls must be so constructed as to bear heavy pressure from any side, and the engineers have worked out a type of construction to meet this requirement. Stations of this type will be built in the center of every block on Wabash Avenue, and the platforms will be but a short distance below the sidewalk level. Underground walks will afford opportunity to cross the streets, or to walk parallel to the car line, past the basement windows of the department stores.

The cars will include the most modern improvements, such as side entrances, to permit the rapid handling of passengers, provided with automatic signals to show the motorman when all the doors are closed. The use of these cars will greatly reduce the length of stops at stations. The plans also provide for the housing of all underground utilities in suitable chambers. Every public service corporation will have its own chamber, as shown on the front-page engraving, in which will be accommodated all of its pipe lines within the subway zone. Particular care will be taken to provide for the future water supply, a very vital provision in the consideration of the future needs of the business district. These chambers will be easily accessible from the street surface, so that it will be a simple matter to inspect or repair the pipe lines of any company. The cost of this gallery construction has been included in the foregoing figures, so that an expenditure of one hundred and twelve millions of dollars will give Chicago a complete traction system, and the best possible provision for her public utilities.

This comprehensive plan is the outcome of several months of investigation by City Engineer John Ericson. The result is a scheme of construction that is well adapted to meet the peculiar needs of a city that has its entire business interest within an area of six square miles. Whatever slight variations may be made in the plans during the progress of construction the scheme for construction as here described will be the general foundation for whatever subways may be built.

### The Current Supplement.

The Garratt flexible railroad locomotive is the subject of the opening article of the current SUPPLEMENT, No. 1795. The salient features of the locomotive are its extreme flexibility and adaptability for operation on steep grades and sharp curves. The mining of tungsten ore is described by Consular Agent Harry A. McBride, of Bilbao. From the beginning, American agriculture has been characterized by its extensiveness rather than its intensiveness. Land has been more abundant than labor. Prof. Homer C. Price contributes an article entitled "The Reorganization of American Farming," in which he points out that the problem which now confronts the American farmer is to adapt his soil to present conditions. William E. Stark presents the first installment of a paper on "Measuring Instruments of Long Ago." "Ilo, a Third Universal Language," is the title of an article describing a universal tongue which is intended to take the place of Esperanto, on which it is an improvement. Prof. Ralph Barton Perry writes on the prophecy of Francis Bacon. A profile puppet-show can be made as described by A. Rose. Some new electrical and physical apparatus are illustrated. Prof. E. A. Minchen reviews some applications of microscopy to practical science and modern knowledge.

---

### The Difference Between a Sanitarium and a Sanatorium.

The words "sanitarium" and "sanatorium" are popularly understood to have the same meaning and are generally used interchangeably, when designating (or describing) places of refuge for sick people but there is, in fact, quite a distinction between the meaning of the two words. In answer to a correspondent on this subject the Literary Digest says:

"The distinction between these words lies in the fact that they are derived from two different Latin roots. 'Sanatorium' is derived from the late Latin *sanatorius*, meaning *health giving*. The term relates specially to 'an institution for treatment of disease or care of invalids, especially an establishment employing natural therapeutic agents or conditions peculiar to the locality, or some specific treatment, or treating particular diseases.' On the other hand, 'sanitarium' is derived from the Latin *sanitas* from *sanus* meaning *whole* or *sound*. 'Sanitarium' relates more specifically to 'a place where the hygienic conditions are preservative of health, as distinguished from one where therapeutic agencies are employed.' Hence it is the province of a 'sanitarium' to preserve health, that of a 'sanatorium' to restore it. Care should be exercised in combining the proper vowels in these two words in order to indicate correctly the derivation."

In our issue of May 14th we published an article on the utilization of wireless telegraphy in connection with a Chalmers-Detroit automobile in the Glidden tour. Through inadvertence, we neglected to state in the article that the wireless installation was devised by Dr. Lee De Forest.

## THE CARTAGO EARTHQUAKE.

BY PROF GUSTAVE MICHAUD, COSTA RICA STATE COLLEGE.

On May 4th, at 6 50 P M, the city of Cartago, former capital of Costa Rica was wiped out of existence by an explosive earthquake which lasted but a few seconds The destructive motion was mainly vertical and began suddenly, that is, without the premonitory shocks which usually give most people time enough to run out from their houses. Immediately after the heavy up-and-down motion came a long series of smaller shocks, among which a gyratory motion was perceptible. The dust raised by the instantaneous fall of houses and public buildings was so great that many people thought they had escaped death by crushing only to die of suffocation. Twenty thousand people

TERRIFIC RESULTS OF THE "EXPLOSIVE" EARTHQUAKE AT CARTAGO, COSTA RICA.

are left without shelter. As the writer is sending this relation (May 7th) 700 corpses have been dug out of the ruins. That number is rapidly increasing. The number of the wounded is not yet known. They are carried daily, by special trains, to San José. The destitution and suffering are intense. Persons who wish to help may do so through the American legation in San José.

During the year 1909 small earthquakes in Cartago had been rather frequent, and the writer, who had a seismograph in the Cartago College, began to send regular reports to the recently founded Strasburg Central Bureau of the International Association of Seismology. On April 13th, 1910, shortly after midnight, came a first warning of the impending catastrophe, in the form of a series of earthquakes, the third of which fissured many houses, destroyed some poorly built walls, and played great havoc among bottles and earthenware. This earthquake was generally felt on the whole Costa Rican plateau. On the following days smaller shocks, mostly of intensity III to V (Rossi and Forel scale) followed at the rate of some three to eight a day. The population in Cartago and San José became alarmed, and erected in the streets and public parks tents and sheds, in which they slept. The shocks had somewhat decreased in number and intensity when the fatal issue came.

Cartago is situated at an altitude of 4,700 feet, at the very foot of the huge volcano Irazu, which towers 11,500 feet above sea level. The Irazu volcano is considered as extinct, the only remnant of its former activity being a few *fumarolles* or steam jets, located at a considerable distance from the now silent and cold craters. At no time before or after the catastrophe have the fumarolles shown any symptom of increased activity. Moreover, the seismograph in Cartago gave for most earthquakes a direction which was almost perpendicular to that of the volcano. However, a few days before the destructive shock, the direction of the earthquakes became variable, and for some of them coincided with that of the Irazu. On May 4th the needle of the apparatus began writing the last chapter of the drama, and while so doing jumped out several times from the glass plate. Then the seismograph, which is a heavy inverted pendulum contained in a box some three feet high, was violently thrown against the wall; the glass plate fell from its shelf, and was broken in two.

Among the public buildings which are in ruins is the beautiful Palace of Peace, a gift of Mr. Andrew Carnegie. The palace had just been completed, the interior only being left unfinished.

## HOW TO ACT IN CASE OF FIRE.

BY PERCY COLLINS.

Perhaps no single ejaculation is capable of producing so instantaneous and so widespread an alarm as the cry of "Fire!" Nor is this surprising when we remember that the fire fiend is each year responsible for an almost incalculable loss, both of life and of property.

Yet of all emergencies, none more than an outbreak of fire imperatively demands a preservation of one's power to act with coolness and decision. Often, by prompt and well-directed action, the threatened catastrophe may be averted, the loss of property and what is still more important, the loss of human life, may be avoided.

Fire drill nowadays has its place in the routine of every well-conducted scholastic establishment, nor can it be doubted that the capacity for prompt and intelligent action thus inculcated in the minds of young people of both sexes has, in emergency, proved the means of preventing appalling disaster. But while this capacity for combined action is very desirable, there seems to be a danger of fostering it at the expense of what one may term "fire education." Every child should be taught by means of precept and experiment, what to do when a fire breaks out in his own house. He should be instructed how to go to work coolly and methodically either to extinguish the flames, or—if necessary—to escape from the building. Lessons of this kind, imparted by practical methods, would become a source of strength in after life and would go far to check the recurrence of fire outbreaks, with their entailed loss of life and capital.

Take, for example, the case of an overturned oil lamp. There is a sudden and alarming blaze, but if action is taken at once, the damage may be confined to the carpet, cloth or what not upon which the lamp actually lies. To throw water on the conflagration is useless. The burning oil will only be forced over a larger area. The aim should be to absorb the oil and smother the flame as much as possible, and this may best be done by means of some non-flammable powder—such as flour, sand, earth from the garden or anything of the kind.

Another point worth remembering is the use of the soda-water syphon as an extinguisher. Suppose that a lamp or candle has ignited a curtain and that the flame has run up the fabric. A syphon of soda water held as shown in the accompanying photograph, and squirted over the flames, will work wonders. Not only does the force with which the liquid leaves the tube allow of its being directed well above the operator's head, but the carbonic-acid gas with which the water is charged helps to deaden the flames.

How to act for one's safety, or to assist another, in the case of burning clothing cannot be better told than in the words of Prof. John Marshall. He says: "If the dress of a woman catches fire, she should at once lie down on the floor, and should crawl in this position either to a bell pull or a door, and call for assistance, or she should roll herself in a rug or blanket. In the event of a man rendering help he should at once lay the patient down, take off his coat and roll her in it, unless he can obtain a blanket or rug or roll her on the carpet. If a woman renders assistance, she must be careful not to allow her own clothing to touch the victim, but to hold a rug or blanket in front of herself while approaching the flames."

Prompt action without rashness or self-balking hurry, is the keynote of success in fighting the fire fiend. This applies especially to those who wake from sleep to find the house on fire. Not a moment should be lost, but there should be no wild rushing from a window to a door and back again. First an attempt should be made to get down the stairs. To escape through passages filled with suffocating smoke, tie a wet handkerchief over the mouth and nose, then crawl on the hands and knees, for the smoke tends to rise with the hot air and will be less dense close to the floor.

But if the whole of the lower part of the house is burning and escape by means of the stairs is impossible, preparations must be made for leaving through the window. Tie all the sheets and blankets together by means of "reef knots," which will not slip no matter how much strain is put upon them. Then drop the bedding or mattress from the window in order that there may be some kind of break in the event of a possible fall. Finally make one end of your improvised fire-escape fast to the bedpost, drop the other end from the window, and after making sure that it reaches to or almost to, the ground go down it boldly hand over hand. It should be added that in the case of inexperienced persons there is always considerable risk of a dangerous fall resulting from this means of exit, therefore it should be undertaken only when all other means of escape have failed.

In conclusion a few words may be added respecting the treatment of burns and scalds prior to the arrival of a doctor. The main point to bear in mind is that the air is to be excluded from the affected part as quickly as possible. This may be done by

(*Concluded on page 451.*)

Blazing oil from overturned lamp extinguished by use of flour.

To avoid drawing burnt or scalded limb from clothing cut apparel away with sharp scissors.

Manner of tying sheets, etc., together to form an escape rope.

Crawling method of escape from passages filled with smoke. Handkerchief holds wet sponge in place.

A syphon makes a handy and an efficient fire extinguisher.

Method of using knotted blanket or sheet rope for escape by windows.

HOW TO ACT IN CASE OF FIRE.

# THE HEAVENS IN JUNE

BY HENRY NORRIS RUSSELL, PH.D.

JUNE, though less exciting from an astronomical standpoint than May, is still a month of more than usual interest

Halley's comet will, of course, still be the main object of attention. At the beginning of the month it is excellently placed for observation, about midway between Regulus and Alphard (α Hydrae) on a dark sky, setting after 11 P M It will however be much less conspicuous than the week before, and will seem to shrink and fade rapidly as it recedes from us. Its distance on the 1st is about fifty million miles, and this increases steadily, at the rate of three and one-half million miles a day—to which the earth's motion in one direction contributes about one and one-half million miles, and the comet's motion in the opposite direction the remainder

Its apparent motion in the sky is slow, for it is moving almost directly away from us It still travels eastward and southward among the stars, continuing the line of its earlier path but very much more slowly, covering only 13 deg during June, and 5 deg during July

During the first ten days of the month it will still be a fine naked-eye object. Then the new moon will begin to flood the evening sky with light, and drown it out By the time she is out of the way again the comet will be 125 million miles from us, and equally far from the sun, so that little can be seen of it without a field glass With the aid of the latter it can probably be followed all through the month

The display which this comet has given us during May is probably the finest of the last fifty years

Curiously enough, its only rival in the last quarter-century is the great comet which appeared so unexpectedly last January This was at one time much brighter than Halley's comet (owing to its close approach to the sun) but its tail was not so long and it was too deep in the evening twilight to be seen to the best advantage

Daniel's comet of 1907, though intrinsically of about the same magnitude as Halley's comet, was never within fifty million miles of the earth, and so never afforded nearly as fine a spectacle

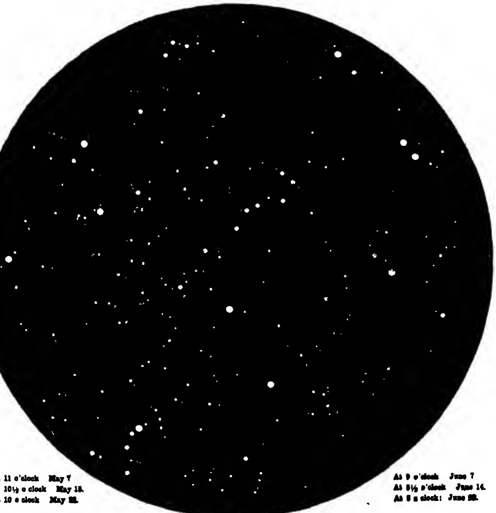
Back of this is a long barren interval The last previous comet which was at all conspicuous to the naked-eye was the great one of 1882 This was one of the grandest on record, and had a tail over 100 million miles in length but this was directed almost away from the earth, so that it never looked more than 35 deg long—as against over 80 deg for Halley's comet before it left the morning sky Before this comes Coggia's comet of 1874, with a tail of 50 deg long but the last comet, fully comparable in appearance with our visitor of this year, is the great comet of 1861, whose tail was at one time 120 deg in apparent length As in the present case, the earth passed through the tail without any sensible effects other than a general illumination of the sky on the night of passage Three years earlier, in 1858, appeared Donati's comet by common consent the finest of the last half of the nineteenth century

Several of these comets, especially that of 1882, were really much larger affairs than Halley's, but the very favorable circumstances of the present return make it comparable, as a spectacle, with any of them, so far as can be judged from the records

The last news at the moment of writing is that its head proved perfectly transparent during its transit across the sun, and that its tail is so much curved in its own plane that the earth did not reach it till long after daybreak on the 19th Before dawn this morning it was a magnificent object, extending from the eastern horizon half way across the sky, till it was lost in the Milky Way Its total length up to the invisible head was fully 130 deg, according to observations here, and 140 deg as seen at the Lick Observatory a few hours later

THE HEAVENS

As our marvelous visitor fades in the western heavens, we may turn once more to the old familiar constellations. In the north, below the Pole, is Cassiopeia, low on the horizon Above her is Cepheus, and higher still the Little Bear, standing poised on its tail above the Pole Between this and the Great Bear are the long coils of Draco Our initial shows the truly formidable aspect of this monster, whose form, coils and all, can be traced with decided likeness among the stars themselves. The two bright stars β and γ in the Dragon's head are very conspicuous. Two others, of which only one is shown on the map, make up with these an irregular quadrilateral The faintest star of this, ν Draconis, is an interesting double, separable with a field-glass of high power—the distance of the components being almost exactly one minute of arc



At 11 o'clock May 7
At 10½ o clock May 15.
At 10 o clock May 22.

At 9 o'clock June 7
At 8½ o'clock June 14.
At 8 o clock: June 22.

At 9½ o'clock: May 29.

NIGHT SKY: MAY AND JUNE.

The star α Draconis, about midway between the bowl of the Little Dipper and the end of the handle of the Great Dipper, is noteworthy as the pole-star of the ancient Egyptians. About the year 3500 B. C. the celestial pole, in the course of its precessional motion, passed very near this star, so that it held the same place in the heavens then that Polaris does to-day

In the northeast we see the great cross of Cygnus, and the brilliant Vega, and due east Altair has just risen Higher up is Hercules, and south of him Ophiuchus, entangled with the Serpent which he carries. Boötes is right overhead, Arcturus being some 20 deg. south of the zenith. Low in the southeast is Scorpio, not yet fully risen. On the right and above is the insignificant group of Libra, and the extensive one of Virgo, now brightened up by Jupiter, in the southwest. Below this, all along the sky from west to south, stretches the mighty length of Hydra, with the Crow and Cup resting upon his back. Due south, far down below Virgo, are many of the stars of the Centaur and the Wolf. Observers in low latitudes, near the tropics, can see below these the two brightest stars of the constellation which, though among the most brilliant in the heavens, have no Greek, Latin, or Arabic names, being too far south to be known to the ancients. The easternmost of the two, Alpha Centauri, is known to all students of astronomy as our nearest neighbor in the heavens—only half as far away as Sirius, which, so far as is now known, comes next.

Farther east, and best seen a little earlier in the evening, is the Southern Cross.

Leo, in the west, and Cancer and Gemini below, complete our list This region of the sky will be the closest watched of all during the month, for the comet is there.

THE PLANETS.

Mercury is morning star all through the month, being best observable about the time of his greatest elongation on the 19th, but as he is then south of the sun, and rises little more than an hour before him, the present opportunity is unfavorable.

Venus is likewise a morning star, rising before 3 A M and very conspicuous.

Mars is an evening star in Gemini and Cancer, setting more than two hours later than the sun.

Jupiter is in Virgo, visible all the evening. He is in quadrature on the 27th, and comes to the meridian at 6 P M

Saturn is morning star in Aries, rising about 2 A. M in the middle of the month On the morning of the 5th he is in extremely close conjunction with Venus, the two being only four minutes of arc apart—too close to be separated by the unaided eye. Unfortunately, the closest approach is at about 9 A. M by eastern standard time, when the planets are invisible in the daylight, and they will be about a quarter of a degree apart at 3 A. M, when we can last see them Observers on the Pacific coast will be able to follow them until they are almost too close to be separated by the eye.

Uranus is in Sagittarius, and crosses the meridian about 2 A. M. in the middle of the month. Neptune is in Gemini, too near the sun to be observed.

The moon is new at 3 A. M on the 7th, in her first quarter at 11 A. M. on the 14th, full at 3 P M. on the 22d, and in her last quarter at 11 P M. on the 29th. She is nearest the earth on the 5th, and farthest away on the 18th. In her course around the heavens she passes Venus and Saturn on the morning of the 4th, very closely These conjunctions, like that of the planets two days later, happen after the sun has risen for the Eastern States, but will be of interest to western observers.

Besides these, she passes Mercury on the 6th, Neptune on the 9th, Mars on the 11th, Jupiter on the 15th, and Uranus on the 24th, none of them closely.

By the addition of magnesia to castor oil, it is possible to obtain a mixture in the form of a powder, which contains fifty per cent of castor oil and produces the therapeutic effects of the pure oil, and yet is odorless and tasteless. The nature of the compound formed was not completely determined until recently. It is now proved that it is not a magnesia soap, but a simple mixture, for the oil can be extracted in [illegible] by ether, or by treatment with [illegible] magnesia.

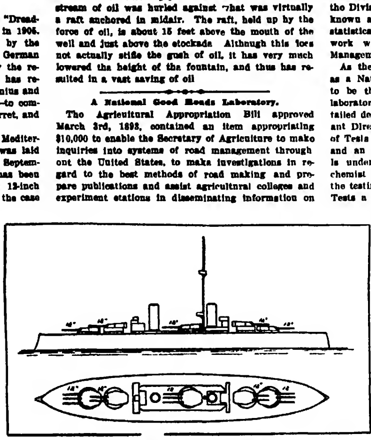
## A 13-GUN SHIP: THE LATEST DREADNOUGHT DEVELOPMENT.

BY PERCIVAL A. HISLAM.

There have been many modifications of the "Dreadnought" design since it was first introduced in 1905. The American modification is distinguished by the center-line arrangement of the gun turrets, the German by the powerful secondary armament and by the reported introduction of the triple turret. It has remained for Italy—the home of constructive genius and the real birthplace of the dreadnought itself—to combine in one ship the twin turret, the triple turret, and the center-line arrangement.

Four ships are under construction for the Mediterranean power. One, the "Dante Alighieri," was laid down last summer, and is to be launched in September. In the case of this vessel, her power has been exaggerated, for instead of carrying twelve 12-inch guns, as reported, she will have only ten. In the case of the other three ships, named "Conte di Cavour," "Leonardo da Vinci," and "Giulio Cesare," it is difficult to say whether their power has been under or over rated. According to first accounts, they were to carry eight 14-inch guns. It now turns out, however, that they will have no fewer than thirteen 12-inch weapons. This is a larger number of single-caliber guns than has ever been mounted in a modern ship, although the Japanese "Satsuma" and "Aki" each carry four 12-inch and ten 10-inch, to say nothing of twelve 6-inch. The arrangement of the guns in the Italian ships is distinctly novel. There will be three three-gun turrets, one forward, one aft, and one amidships, while a twin turret will be placed forward and aft, so as to bring its guns to bear over the lower turret. There will thus be a full broadside of thirteen 12-inch guns, with a fore-and-aft fire of five. The secondary battery will consist of eighteen 4.7 inch rapid-fire guns, besides the same number of 3 inch. Three under-water torpedo tubes will be fitted. The displacement will be 24,000 tons, the main armor belt 12 inches thick, and the speed 22 knots.

The arrangement of the armament in the "Dante Alighieri" is precisely the same as that in the other three ships, save that the midship turret is suppressed, and that the after turrets are on a lower level than those forward. As will be seen from the accompanying sketch, the deck runs straight from bow to stern in the three other ships. The "Dante" will have a displacement of 18,300 tons and a speed of 23 knots. The four ships are to be completed in 1913.



NEW ITALIAN BATTLESHIPS WHICH WILL BE THE FIRST TO CARRY THIRTEEN TWELVE-INCH GUNS.

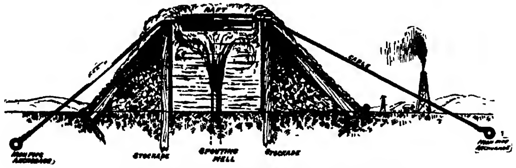
## HOW THE LAKEVIEW GUSHER WAS CAPPED.

BY E. C. CARR.

Last week's issue of the SCIENTIFIC AMERICAN contained a description of an oil well in the midway district near Bakersfield, Cal., which on March 15th suddenly blew out the drilling tools and became the Lakeview Gusher, the largest oil gusher in California, blowing out at the rate of over 40,000 barrels of heavy crude oil a day. The force of the gas pressure was so terrific that the derrick was ripped to pieces, and oil spray was literally sent for miles in every direction. How to cap this well was a serious problem. For several weeks no attempt whatever was made to check the flow. A tentative attack was then made to fasten down a wooden roof over the head of the well. Although the roof was made of 16 by 16 timbers, the gusher tore them to splinters.

The following plan was then successfully adopted:

The gusher had by this time broken out in several small oil fountains in addition to the main stream. These additional openings were smothered by means of successive bulwarks of brush and sand. A stockade of heavy planks was then built around the spouting well. The walls of the stockade were 15 feet high. On one side of the stockade a slanting runway was constructed. A heavy raft 15 by 20 (approximately) was then built, resting on this runway like a ship on the ways. Heavy wire cables were fastened to the four corners of the raft. The cables at the two lower corners were made fast to heavy pipes buried 12 feet under ground. The cables attached to the upper corners of the raft, as it lay on the ways, were run over the top of the stockade. At a favorable [illegible] these upper cables were hauled taut, and the raft was [illegible] into position like a hatch. The two lines [illegible] bles, which had served to haul up the raft, were then made fast to buried pipes. The result was that the stream of oil was hurled against what was virtually a raft anchored in midair. The raft, held up by the force of oil, is about 15 feet above the mouth of the well and just above the stockade. Although this does not actually stifle the gush of oil, it has very much lowered the height of the fountain, and thus has resulted in a vast saving of oil.



ARRANGEMENT OF STOCKADE AND RAFT WITH WHICH THE LAKEVIEW GUSHER WAS CAPPED.

### A National Good Roads Laboratory.

The Agricultural Appropriation Bill approved March 3rd, 1893, contained an item appropriating $10,000 to enable the Secretary of Agriculture to make inquiries into systems of road management throughout the United States, to make investigations in regard to the best methods of road making and prepare publications and assist agricultural colleges and experiment stations in disseminating information on this subject. In pursuance of this authority, the Office of Road Inquiry was established.

During the next two fiscal years the appropriations and the wording of the bill remained the same. The appropriation for the fiscal year 1897 was reduced to $8,000, and a provision was added authorizing the investigation of road-making materials in the several States. The appropriation remained $8,000 annually during the fiscal years 1898, 1899, and 1900, and no change was made in the wording of the bill, although the name of the office was changed from "Road Inquiry" to "Public Road Inquiries" in the fiscal year 1899.

The Agricultural Bill for 1901 carried an appropriation for $14,000 and provided for conducting experiments in the city of Washington and elsewhere and collecting, digesting, reporting, and illustrating the results of such experiments. The appropriation for 1902 was $20,000, and the bill provided for the investigation of the chemical and physical character of road materials. The language of the appropriation bills has remained practically unchanged up to the present time, except that the name of the office was changed from "Public Road Inquiries" to the "Office of Public Roads" and a statutory organization was provided in the Agricultural Bill approved March 3rd, 1905. In the appropriation bill for 1909, the rent or purchase of road-making machinery was forbidden. The total appropriations to the fiscal year 1909 inclusive amount to $473,440. The estimate for 1909-10 as approved by the Secretary of Agriculture is for $136,450.

The Office of Public Roads is under the jurisdiction of the National Department of Agriculture as shown above. It has no administrative duties and exercises no control whatever over the roads of the United States, its functions being entirely scientific and educational. No appropriations are made by the national government for roads except on government reservations. At the present time there are sixty-seven officials and employees on the rolls of the office. The work of the office is divided into three branches, namely, the laboratory work, which is organized as the Division of Tests, the engineering work, which is known as the Highway Division, and the economic, statistical, road management, and miscellaneous work which is organized as the Division of Road Management.

As the Division of Tests, which may be regarded as a National Good Roads Laboratory, is considered to be the most completely equipped road material laboratory in the world we give the following detailed description of the plant and work. The Assistant Director and Chemist has charge of the Division of Tests. He has as his assistants a testing engineer and an assistant chemist. The chemical laboratory is under the immediate direction of the assistant chemist and the physical testing of materials is under the testing engineer. There is also in the Division of Tests a petrographic laboratory with a petrographer in charge. The routine testing of materials conducted by the Division of Tests consists of microscopic and chemical analyses of specimens to determine their mineral composition and proper classification, and physical tests to determine their cementing value, hardness, toughness, resistance to wear, water absorption, and density. (Bulletin 79, Bureau of Chemistry.)

In addition to the routine tests special studies are made regarding the use and composition of asphalts, oils, tars, compounds, various emulsions, and salt solutions, with the view of preventing dust and preserving road surfaces. (Bulletin No. 34.) Other investigations include research into the decomposition of rock powders (Bulletin No. 28, Circular No. 38 and Farmers' Bulletin No. 239), the testing of clays for use in paving brick, burnt-clay and sand-clay roads (Bulletin No. 27 and Farmers' Bulletin No. 311), and the corrosion of iron culverts, bridges, and fence wire (Bulletin No. 30 and Farmers' Bulletin No. 239).

The equipment for the physical testing laboratory is as follows:

Large impact machine for testing paving brick, impact machine for testing binding power of rock dust, impact machine for testing the toughness of rocks, Olsen testing machine for tensile, cross bending and compression tests, capacity 20,000 pounds, Riehle testing machine for testing tensile, cross-bending, and compressive strengths, capacity 200,000 pounds, delicate platform scales, hydraulic machine for molding briquettes, torsion balance, abrasion machine for testing resistance to wear of rocks, vacuum pump, diamond saw and grinding laps for making thin rock sections for microscopic examinations, ball mill for grinding rock samples into powder, centrifugal pump, diamond core drill, small rock crusher, grinding disk for testing the hardness of rock samples, battery of pebble mills for pulverizing rock powders, Westinghouse air compressor, hot air bath, gas furnace, and a complete cement testing outfit consisting of a Fairbanks torsion machine, Gillmore's needles, standard sieves, briquette molds, soaking tanks, etc.

The equipment for the machine shop where testing machines and other apparatus are made and repaired is as follows:

Speed lathe, engine lathe, drill press, power hack saw, precision lathe, saw table, universal trimmer. The chemical laboratory is equipped with the necessary chemical apparatus used in making analyses of rocks, clays, cements, and bituminous substances. It is provided with compressed air, vacuum, gas, hot and cold water, steam, and electricity. The petrographic laboratory is provided with a petrographic microscope of the latest Fuess model, which besides the usual attachments is provided with a revolving analyzer in the tube to aid in the determination of very low doubly refracting mineral, and a Schwartzman scale for the measurement of optical axial angles. The methods used for examining and classifying rocks are fully set forth in Bulletin No. 31.

The road material laboratory was established in December, 1900, and from that time until November 30th, 1908, 3,018 samples of road material were tested from practically every State in the Union. The results of tests made up to January 1st, 1908, and a brief description of the present methods of making routine tests are shown on Form No. 28.

# NEW TWO-CYCLE MOTORS

## DEFECTS OF THE TWO-CYCLE ENGINE AND HOW THEY ARE OVERCOME

A belief is growing among gas engine experts that the greatest improvements in gas and gasoline motors must come in the future from some type of engine which gets increased power from its cylinders by eliminating the idle revolution of the four-cycle type It is conceded that four-cycle design has practically reached the limit of its possibilities the advent of the automobile having drawn the services of the brightest men in the gas engine field, the result of whose work is seen to-day in the splendid examples of gas engines found in even the cheaper kind of automobiles However many designers feel as was expressed by one prominent engineer, that "It is inconceivable that the four-stroke cycle with its small utilization of one-half of the piston strokes will be accepted as the finality of development, the two-stroke cycle as now applied is equally unsatisfying for reasons that are familiar to all students of the question"

It is apparent that the chief efforts toward improvement are now being made with a view to eliminating the defects heretofore common to the two-cycle type

The chief defects of the usual two-cycle engine may be summed up as follows

1 The explosive mixture is taken into the crank case resulting in leakage and in possible explosions in the base

2 The new charge comes into direct contact with the hot burned gases, causing possible pre-ignition and some loss of gas at the exhaust

3 The charge is not large enough in volume because the crank case is an altogether inefficient compressor on account of its very large clearance This means a small charge and also a large percentage of dead gas left in the cylinder

4 The power is not increased materially by the double number of explosions because of the weak charges and poor economy

Several recent two-cycle engines meet these defects in different ways The Newcomb engine was recently exhibited before the Automobile Club of America This is a two-cycle engine using the crank case to supply air only This air blows out the previous charge and furnishes oxygen to burn the next charge of fuel The fuel is injected directly into the cylinder from a plunger pump, the quantity being controlled by regulating the stroke of the pump The gasoline is directed downward into a small cup on the head of the piston When the piston rises this cup or pocket is in the vicinity of the spark plug so that there is always an ignitable mixture near the plug even when running on very light load This arrangement avoids several of the defects of ordinary two-cycle engines The charge is limited, however by the amount of air which can be supplied from the crank case, which would scarcely exceed 75 per cent of the displacement of the piston, leaving the other 25 per cent and the clearance space filled with burned gas This engine will undoubtedly be more powerful, economical, and reliable than the ordinary two-cycle motor

Another improved type of two-cycle engine is that employing a differential piston This engine leaves out the crank case entirely as a means of supplying

Fig 1.—Shertt two cycle motor.

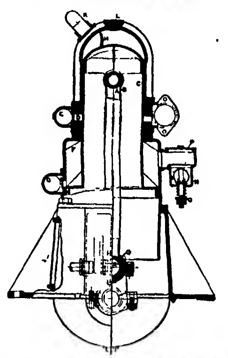


Fig. 2.—Longitudinal section through the Broderick two-cycle motor

the charge or air and compresses the charge initially in an annular chamber formed by a differential or two-diameter piston. Two cylinders are worked together, the lower piston of one compressing the charge for the other This permits getting a full charge and large capacity, though the loss of fuel through the exhaust is likely to be greater The leakage loss and base firing are eliminated This type of motor is used on the Elmore automobile and a light-weight engine weighing but 3½ pounds per horse-power and constructed after the design of J W Broderick is now being manufactured for aeroplanes and other aeronautic purposes.

A good idea of the method of operation of this motor can be had from the diagrams we reproduce The cross-section of one of the cylinders shows the large compressor piston on the lower end of the working piston *C* On the down stroke the large piston draws in a charge of gas from the carbureter through the automatic inlet valve *M* On the up stroke it compresses this charge in the chamber *F* above it and in the pipe *G* leading across to the inlet port of the second cylinder Just before the piston of the second cylinder opens the exhaust port, it uncovers the inlet port *D* and the charge compressed in the transfer pipe *G E* leading from cylinder one to cylinder two, passes into the cylinder and is directed upward by the deflector *H* In the motor shown, the connecting rods *A* are of steel tubing for the purpose of saving weight. The spark plugs are located in the dome-shaped cylinder heads, where they are most effective in igniting the mixture This type of two-cycle motor offers the advantage that there is no possibility of leakage of the initial compression after the crank-shaft bearings have become worn, and there is no necessity of making these bearings heavier and longer than usual for the prevention of undue wear Neither is there any trouble from back fires in the crank case, which sometimes cause serious damage

The new cycle motor is a recent invention of C A. Dawley, member of the American Society of Mechanical Engineers This engine has some features of both of those described above It uses a differential piston and handles the charge in an annular chamber, but it also compresses air in the crank case Owing to the enlarged diameter of the piston in the crank case, the air supply is in excess of the piston displacement. The air displaces the exhaust and scavenges the cylinder before the new charge is admitted The admission of the new charge is controlled by the valve *F* in Fig. 5, and the timing is such as to introduce the charge after the cylinder is cleared of burned gases, but before compression commences. This evidently will give a full charge of air and fuel and prevent any loss of fuel or premature ignition When used on gasoline this engine may use a carbureter, in which case an extra rich mixture would be drawn into chamber *B*, while the additional air required for combustion would come from the crank case Or a fuel pump may be used as in the Newcomb engine, except that in this case the gasoline would be delivered into port *M* and then blown into the cylinder by the charge of

# The Home Laboratory

## A ROUGH AND READY GALVANIC BATTERY.

BY A. J. JARMAN

The best battery for experimental work in the workshop or laboratory is one of the rough-and-ready type that will give a moderate current of electricity of say three or four amperes with an electromotive force of 1.5 to 2 volts. Such a battery is suited for the exciting of a powerful electromagnet, for magnetizing purposes, operating an induction coil, and for electro silver plating, electro brassing, or electro coppering either by the hot or cold process, and for electro gilding. The following description will enable anyone who can handle woodworking tools to construct such a battery consisting of two cells capable of being coupled so as to give the current of one large cell or in series so as to yield the current of one cell and the electromotive force of two. This latter plan is the one best suited for coppering, brassing or electro nickeling. This type of battery has been used, and is still used by the writer for all the purposes mentioned, for over five years, so it has been put well to the test of experience.

The wood used in making the battery must be thoroughly well seasoned. An old board that has been kept years in an office or a loft will prove to be just the thing required. The board should be 1 inch thick. Cut a strip 5 feet long and 8 inches wide. Plane this smooth all over and then cut three pieces 13½ inches long, and three pieces 5½ inches long. The latter will form the ends and central division of the battery. The side pieces must be grooved so as to receive these pieces with a very nice fitting joint as shown in Fig. 1. The bottom piece must be made as shown in Fig. 2, with two pieces of wood cut exactly 5 inches square, this also being the inside measurement of each cell. These squares must be held in place by means of screws that are inserted from the underside of the bottom board and penetrate to within ¼ inch of the outer surface of the squares. They should also be coated with a thick shellac varnish (not glue) before being fastened in place. The grooves in the side pieces and the ends of the division pieces must also be well coated with thick shellac varnish, after which the pieces should be driven tightly together and held by nails or screws. Nails driven diagonally make the best job because they will draw the woodwork together more firmly than screws, and resist direct strain better. The object of using shellac is to insure a perfect acid-proof joint, and the 5-inch square pieces where pressed into position form a bottom so firm that no acid liquid will penetrate.

When the battery has been put together it must be lined on the inside with a coating of burning hot pitch. Use an old saucepan to melt the pitch in. Pour some into one of the cells and tilt the battery first one side then another until all four sides have been submitted to the hot pitch. Pour the pitch back into the saucepan, take a strip of square or flat iron, make one end red hot, and press this well into the corners and around the joints at the bottom, so as to secure a perfect coating of pitch at these joints. Now pour the hot pitch into the cell again so as to be sure that all parts are well covered. Treat the second cell in like manner. Having the case now well put together, finish the outside by giving it two coats of shellac varnish mixed with crocus (oxide of iron). This paint will resist the acid solution used in the cells and give quite a nice finish to the work. To complete the battery procure two zinc cylinders 7 inches high, 3½ inches inside diameter, and ⅛ inch thick. Also two round porous pots 3 inches diameter and 7 inches high. Also two carbon plates or blocks 7 or 8 inches long, ½ inch thick, and 2 inches wide. Attach two brass battery clamps to these with a strip of sheet copper folded over the top of the carbon block. This is an important item. Its use will protect the brass clamp from being corroded by the acids. The zinc cylinders can be purchased with a copper strip and binding screw attached. The zinc cylinders must be amalgamated by dipping them into sulphuric acid 1 part, water 8 parts, and then rubbing all over inside and outside with quicksilver. Place these zincs in the wooden vessel. Make up a mixture of sulphuric acid 1 pint, water 8 pints in a stoneware pitcher, and allow it to become cold. In another vessel make a mixture of water 4 pints, bichromate of sodium or potassium 12 ounces, sulphuric acid half a pint. Allow this also to become cold. The battery is now charged by pouring the bichromate mixture into the porous pots, around the carbon blocks, and then pouring the sulphuric acid mixture into the outside space around the zinc cylinders. The battery is now ready for any purpose required and will keep in good action for about six hours continuously. When not in use the zinc cylinders must be removed and placed into a stoneware crock filled with water, and the bichromate mixture must be returned to the vessel it was made in. The carbon block can also be stood on end upon blotting paper or in a wide mouthed pickle bottle. The sulphuric acid mixture can be allowed to remain in the wooden battery cells. For intermittent use such a battery will work well for months and meet every requirement for small work, either in the workshop or laboratory. No amount of hard use will injure it, if well put together as described. No acid solutions will affect it, although the liquid may be left in the cells year in and year out.

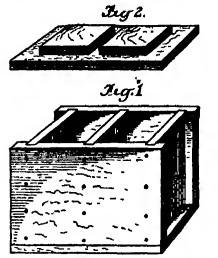
Fig. 1



A ROUGH AND READY GALVANIC BATTERY

## SAFE GASOLINE TANKS

BY DR. P. W. BRENEH

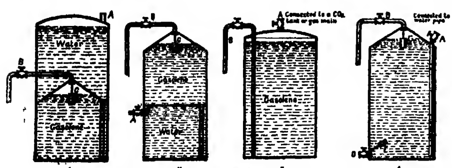
As gasoline explosions are due to a mixture of gasoline vapor with air (accidentally ignited, of course) I think the air in a gasoline tank could well be replaced either by water or a non-oxidizing gas such as carbon dioxide, after the manner here illustrated.

In the first two designs water is used. In Fig. 1 the weight of the water forces the gasoline out of the lower tank through the stopcock B. The valve C is so constructed that it floats when the water reaches it, closes the opening, and thus prevents the water from flowing out. To refill the tank with gasoline, a suction pump is connected to the stopcock A and the gasoline is siphoned into the lower compartment through the stop-cock B. The latter prevents the gasoline from escaping.

Fig. 2 is practically the same, but to discharge the gasoline through the stopcock B air must be pumped into the lower part to force the water into the gasoline tank above. To refill this tank with gasoline, the stopcock at A is opened, letting the air out and the weight of the water then siphons the gasoline into the tank above through the valve and stopcock B.

In Fig. 3 a carbon dioxide tank is connected to the pipe A and the pressure of the gas then forces the gasoline out through the pipe B.

In Fig. 4 the stopcock A is connected to the water main or pipe when the pressure of the water forces the gasoline out through the stopcock B. The valve C prevents the water from escaping into the gasoline cans through the stopcock B. To refill the tank, the stopcock A is closed and stopcock D is opened, and the water flowing out through the latter will draw the gasoline into the tank through stopcock B. The valve B is adjusted to sink in gasoline and thus close the outlet, preventing escape of gasoline through the stopcock D.



SIMPLE METHODS OF MAKING GASOLINE TANKS SAFE.

## PLUG CONNECTOR

To make a plug connector for use in an electric light socket, all that is required is a burned out incandescent lamp and a number of feet of heavy lamp cord. Break the glass globe out of the lamp, leaving only the base. Then break away the glass tube that protects the leading-in wires, being careful not to injure them. Now untwist about a foot of the lamp cord, scrape the ends clean and slip a short length of rubber tubing over each end. Solder the ends to the leading-in wires in the lamp base and then push the rubber tubes down over the joints. Fill the socket with plaster of Paris, letting it project up above the top of the plug about an inch so as to form an insulated top to screw the plug in by. This plug connector is suitable for small motors, portable lamps, and any other apparatus that draws only a small current. It cannot be used for large currents as the heavy current would fuse the leading-in wires in the plug.

## A SIMPLE APPARATUS FOR EMPTYING CARBOYS

BY H. N. F. CLARKE.

A very simple, effective and easily set up apparatus for emptying carboys of acid, etc., may be made in the following way from materials found in every laboratory. This will be found to be far superior to the acid pump or the old-fashioned method of tilting the carboy, catching the liquid in a jug, and then pouring it into bottles. For no fumes can escape, and this is an important factor when dealing with strong ammonia or hydrochloric acid (spirits of salts).

Say one wishes to fill with hydrochloric acid or another liquid any number of bottles from a carboy.

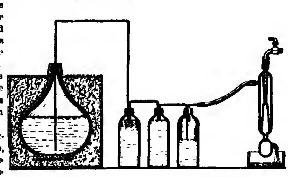
Fit every one of the bottles with two-holed rubber corks and then through each hole put a piece of glass tubing bent in the form of a right angle with sides about three inches long. Connect one piece of glass tubing in one bottle to another piece in another bottle with a small piece of rubber tubing, the free piece of this bottle with another piece in another bottle, and so on until you have all the bottles connected up in one straight line.

Connect the free tube at one end of the line with a piece of rubber tubing to a long bent glass tube passing to the bottom of the carboy.

Attach the other free tube at the other end of the row of bottles to a glass filter pump or any other suction apparatus with a piece of thick walled rubber tubing. Then we have the apparatus as illustrated herewith.

Turn on the water tap connected with the filter pump and the acid will be drawn up the tube leading from the carboy and into the first bottle. As soon as this is filled the acid will run into the second bottle, and so on until the carboy is empty or the requisite number of bottles are filled.

If one hasn't many corks all that is necessary is to fill say three or four bottles. When these are filled they can be disconnected and others put in their place. But it must not be forgotten to turn off the water tap and so stop the flow of liquid before making the change.



APPARATUS FOR EMPTYING CARBOYS

If the liquid in the carboy is sulphuric acid (oil of vitriol) or any other liquid that attacks rubber the two bent tubes connecting bottle to bottle may be made in one piece and if care is taken to push the ends of the tubes below the end of the corks the liquid won't reach up to them and so they will not be hurt in the slightest. In fact no rubber connections may be made use of except from the suction pump to one end of the line of bottles though, of course it is more convenient to use them.

A glass filter pump is the best to use because any fumes that may perhaps come over have no corroding effect on it, as they would have on a metal one

### MAKING YOUR OWN PERFUMERY.

BY A. H. ATKINSON

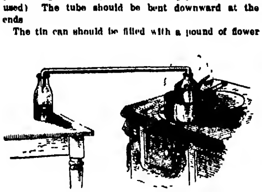
The manufacture of perfumery has always seemed a difficult process to many, and without doubt the blending of certain kinds of perfumes is a matter of much scientific and skillful manipulation, but on the other hand, the most commonly used perfumes can be made at home with simple apparatus and without much expense or trouble In many parts of the country, flowers are so abundant that one can harvest all that are needed for manufacturing at home perfumes enough for a year's use

A perfume garden should prove as profitable as one of fruits or vegetables We plant gardens for cut flowers and for flower seeds, but few raise flowers for perfume making Enough perfumery is sold in this country annually to make a yearly tax of nearly ten dollars on every family This amount is not evenly distributed, but each woman spends enough to make it worth while, if she has the garden space to try a hand at making her perfumes at home

One must devote time to the cultivation of certain flowers which thrive luxuriantly in the vicinity In many parts of the country roses thrive so luxuriantly that fields can be sown with them, and an abundant crop raised In other sections the rose is too slow-growing for this purpose, but the violet takes its place Again, it must be the jasmine, the tuberose, the orange blossom, or lavender Whatever flower it is that thrives and possesses delicate but powerful fragrance should be chosen for the work

Direct distillation is the most satisfactory way of making perfumery The still is a simple affair and it can be made out of articles found in the average home Take an ordinary tin oil can, scour it, and purify it of all oil odors Stop the spout completely, and fit a cork in the top through which the oil is poured From a hardware store get four feet of copper tubing (tin or galvanized iron pipe may also be used) The tube should be bent downward at the ends

The tin can should be filled with a pound of flower



HOME-MADE PERFUME STILL.

petals gathered fresh in the early morning Pour over these petals eight fluid ounces of alcohol Then put the can in a saucepan half filled with water, and place on a stove, where the water can be kept at the boiling point. A hole should be cut through the cork of the can just large enough to receive the metal tube. Place a quart jar on a table nearby, and insert in it the other end of the tubing This jar should not be sealed, or distillation will not go on properly

When the water boils, the alcohol in the can is heated, and this process extracts the perfume from the flower petals, and gradually causes distillation through the tube into the cold jar on the table The alcohol thus distilled will carry with it the true attar of the flowers Alcohol has a peculiar property of extracting and holding the scent of flowers As fast as distillation goes on, the contents of the jar should be emptied into glass bottles and securely corked and sealed with paraffin In blending perfumes of several flowers, do the mixing after each one has been distilled separately Do not mix the flowers in one still

Another method of using this still is to employ water instead of alcohol for distillation Instead of attar we get the essential oil of the flowers, and this rises and floats on the surface of the water in small globules, which must be skimmed off carefully, and immediately bottled and kept cool and air tight. When sufficient oil is obtained, it should be mixed with alcohol to retain the odor indefinitely One may distill with water any number of kinds of flowers, and with the essential oil properly bottled, blended perfumes can then be made A few drops of several kinds of oil are poured into a bottle containing a certain amount of alcohol, and when shaken thoroughly one has a delicious fragrance for home use For instance, eau de cologne is made by pouring into a glass bottle a pint of alcohol, and adding half a drachm of home-made attar of rosemary and twenty drops each of the attar of orange peel lemon peel, and bergamot peel The distillation of these fruit peels is another desirable home industry Cut up fresh orange or lemon peel and place it in water in the tin can, and heat as for use in flower leaves The essential oil of these peels will then be gradually distilled into the other receptacle Skim off the globules, and confine in corked bottles.

Besides distillation, we have the process of absorption, which anyone can do at home with little trouble and expense It is slightly more complicated, but it will extract the perfume of more delicate flowers, such as the violets, with greater success. This process consists of covering two large shallow pans or soup plates with a layer of melted suet. The layer should be half an inch or more thick When the fat has hardened, gather the violets, jasmine, or tuberose flowers, and cover the suet thickly with them Then place one plate over the other, and force down firmly. Wrap the plates tightly in paper, so that the perfume will all be retained In twenty-four hours the suet will have absorbed nearly all the perfume Then quickly remove the dead petals, and replace with more fresh ones Repeat this operation for several days or even for a week, so as to secure a strong supply of odors. When enough petals have been robbed of their odor, remove the top plate and cut the suet into small pieces, and drop them into a wide-mouthed bottle or glass jar containing alcohol The transference should be made as quickly as possible, and with least exposure to the air Then close the bottle or jar, and seal with paraffin to make air tight As the suet absorbed the fragrance of the petals, so will the alcohol rob the suet of its concentrated extract. Every day the bottle should be shaken a little, and in a fortnight the alcohol should be poured off through a strainer into bottles and corked

Besides making the liquid perfumes, one should consider sachet powders and perfumed pastes. These have their use in every household A rose paste is made by steeping rose leaves in water, and pounding with a mortar until reduced to a paste. This maceration should be thorough, and can be done with an ordinary rolling pin Now add a drop or two of your home-made attar of rose, and permit the paste to dry in an air-tight receptacle The paste will grow quite hard, and can then be cut into any shape desired A piece placed in a drawer will scent the place for a long time If the pieces not in use are kept air-tight they will retain fragrance indefinitely, and will always be ready for instant use Laid in linen and clothes presses, they add that subtle fragrance to the fabrics which so many like

Sachet powders are as numerous and as varied in fragrance as colognes. One may compound them out of flower petals, spices, and perfumes to suit individual preferences The art of making sachets is very simple and inexpensive If we add to these attars and essential oils such simple articles purchasable at any drug store, as iris root, musk, and cochineal (the last for coloring only) and such spices as cloves, cinnamon, and ginger, we have all the materials that a small laboratory requires for making a dozen kinds of popular sachets. Lavender seeds raised and cured at home make a sachet suitable for those who like this odor Another is manufactured by mixing iris root and ground cloves with a little musk and attar of roses, the whole moistened with a little alcohol, and then rolled and kneaded into a paste, which in time grows quite stiff A few pieces of this distributed around in the clothes press will add a delicious odor to garments. For gifts, appropriate bottles and ribbons or boxes may be purchased cheaply at the stores, or silk and damask can be obtained for concealing sachet or perfumed pastes, and pin cushions may be made and scented indefinitely by inclosing a good piece of the perfumed paste in the center

### AN EXPERIMENT IN SOUND.

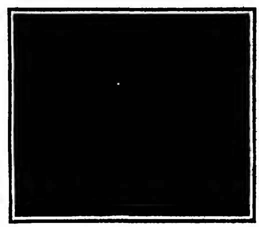
BY W. E. CARR.

Those who have had the good fortune to travel through a virgin tropical forest could hardly fail to have been impressed by the death-like stillness which pervades all nature between the hours of 1 and 4 P M This is the thermal noon of these regions, when all life, weary with the battle with the terrible heat, seeks repose in a much-needed siesta No sound is heard save perhaps the slight rustling of a leaf, or the plaintive grunt of a tardogradus as he answers the call of his mate, or reaches out for a new caucho leaf with which to satisfy a never-ending appetite

Under these circumstances Humboldt, the great German traveler, who was camping twelve miles from the falls of the Orinoco River, was astonished to find that no sound from this source reached his ear, while eight hours later, during the night, when the woods were rendered a perfect pandemonium by the shrieks of panther, jaguar, and monkey, the sound of falling waters broke with astonishing clearness upon his ear. What is the explanation of this phenomenon? And why, for example, do the citizens of Washington hear so distinctly, at night, the heavy trains as they pass over the Potomac railroad bridge, while during a calm, sunshiny day they listen in vain for the noise of the moving cars? The very natural explanation that the noise of the day traffic masks the sound of the cars does not suffice, as the experience of Humboldt proves. Some light is thrown upon this problem by a recital of the experience of the writer, when on a hot day placed upon a bluff forty or fifty feet high, and overlooking a large, level, low ground, from which [illegible] see the hunters leading their game [illegible] discharge, and the falling game, but [illegible] reached his ears; while again, say five minutes later, with conditions apparently unchanged, even the conversation of the sportsmen became audible.

Prof Tyndall has described this phenomenon, and attributed it to large masses of air, different in temperature and density from the surrounding atmosphere, drifting in between the ear and the source of sound These "ear clouds," for veritable clouds they are, as far as the human ear is concerned, though perfectly transparent to the eye, possess in a marvelous degree the faculty of reflecting sound waves.

Following is the description of a simple experiment, which, if thoroughly understood in all its bearings, will enable one to explain some of the most apparently complex phenomena in nature. Everything has its own period of vibration, that is, the rate at which it naturally swings, or vibrates—not only a tuning fork, but a column of air, and even a house, a tree, or a ship Other things being equal, the longer the object the slower the swing; just as a tuning fork with long prongs swings slower, that is, gives a lower note, than one with short prongs, which swings faster and gives a higher note. Now take a fork giving the note C, which is due to 512 vibrations per second, energize it by bowing or by striking it with a hammer, and hold the fork before the mouth of a bottle, say 6 inches deep and 2 inches in diameter. Instantly you hear an increase in the intensity of the sound, because the column of air inclosed by such a bottle will vibrate the same number of times per second as the fork. Now hold a second similar bottle between the prongs of the fork, as in the accompanying photograph,



AN EXPERIMENT IN SOUND INTERFERENCE.

and the sound is practically extinguished, because the crests of the waves entering one bottle coincide with the troughs of those entering the other Under these circumstances there is always interference, or silence Now introduce a piece of cardboard between the mouth of the bottle and the vibrating prong, the conditions of interference are destroyed, and loudness is restored. But an ear cloud is quite as effective as a piece of cardboard Place a burning match or a hot poker beneath the mouth of either one of the bottles, and as the thin layer of warm air reaches the opening it acts as a curtain, reflects the sound waves, and instantly the loudness of the fork is restored Thus is demonstrated a significant and wonderful fact, the power of a thin layer of air to reflect sound quite as effectively as a board. Now, what are the physical conditions obtaining during the day between the ears of the citizens of Washington and the bridge over the Potomac River? The sun is shining, the atmosphere is still, a hot stratum of air rises from a metal roof, another slightly cooler from a grass plot, another of a different temperature from a concrete street, etc. Many strata of different temperatures intervene between the ear and the bridge. As we have just observed the effect of one stratum, we can readily realize that several would possess the power of completely extinguishing the noise of the moving trains. At night, on the contrary, the air is homogeneous, the waves are unimpeded and strike the ear with astonishing clearness.

Bearing in mind these facts, many apparently inexplicable phenomena become as clear as the noonday sun.

---

The use of towing tanks to determine the best forms of ships is much older than is generally supposed. A recent article in Engineering describes work of this character done by David Napier on a model of a channel steamer, the "Rob Roy," which in 1818 inaugurated the [illegible] service between [illegible] and Belfast. The [illegible] we are told, were [illegible] 12 inches wide, [illegible]

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

COMBINED CORSET-COVER AND BUST-SUPPORTER.—JENNIE MARK and EMMA MARK, New York, N. Y. The object of this invention is to provide a new and improved corset cover and bust supporter, designed to be worn over the corset to form a corset cover, and arranged to properly support the bust and enabling the wearer to adjust the parts for the purpose and without danger of displaying the adjusting devices through shirt waists of fine thin texture.

FASTENER FOR GLOVES AND OTHER ARTICLES.—L. W. BROWN, St. Louis, Mo. If a glove fits closely it is very difficult to effect a closure of the ordinary spring button clasp, the half sections of which are respectively secured on the vent flaps of the glove. To enable the easy, quick, and reliable closure of the two parts of a spring button clasp, a novel attachment has been provided and constitutes the feature of improvement.

HAT HOLDER.—E. J. GUILLARD, New York, N. Y. One embodiment of this invention comprises a casing, adapted to be secured in a hat, having therein spring controlled slides, provided with holding members guided on the inner rim of the casing, the action of the said holding members being substantially controlled by manually operated means connected with the said slides in the casing.

### Electrical Devices.

ELECTRIC FURNACE.—H. W. HIXON, Philadelphia, Pa. An object here is to provide a device in which the zinc is fed into the furnace, the top of which is kept closed so that the zinc vapor is forced to escape at a lower point, preferably the tap hole. To this end Mr. Hixon provides a furnace with a top of double construction so that an upper door may be opened and a charge fed in while the lower door is shut, thereby keeping the zinc vapors within the furnace.

### Of Interest to Farmers.

BUG AND WORM KILLING MACHINE.—L. THORTVEDT, Glyndon, Minn. This invention relates to mechanical means for removing and killing bugs and worms, that infest plants or bushes while growing, and the object is to provide details of construction for a power actuated machine which is convenient to control while operating, and that is particularly well adapted for the removal and killing of bugs upon growing potato vines.

AUTOMOBILE MOWING-MACHINE.—C. G. DELANO, Berkley, Mass. This invention provides mechanism for propelling and operating a mower by power, provides traction mechanism for the mower adapted to be guided in rear of cutter bar, provides mechanism disposed in operative position in advance of traction mechanism; provides means for lifting the bar off the surface of the ground to avoid obstacles thereon; provides traction mechanism which may be utilized for miscellaneous power purposes, and a suitable reciprocating mechanism for the knives of the bar and operating connections therewith.

COMBINED HAY TEDDER AND MOWER.—W. F. SCHANBIAN, Lima, Ohio. An object of the inventor is to provide means whereby the hay can be tedded and turned during the mowing operation. A further object is to provide a device rapid and clean in its operation. Still further to provide means for adjusting the height of the tedder frame from the ground.

STALK-CUTTER.—J. MICHALKA and F. A. MICHALKA, Cameron, Texas. A purpose of the invention is to provide a machine that will not only cut standing stalks at a point near the ground, but which will practically at the same time cut the stalks in very short pieces, rendering it easy to plow the stalks under to enrich the soil, while any fragments that may remain on the surface will not in any manner interfere with the cultivation of a crop.

### Of General Interest.

ANCHOR.—J. W. NEAL, Koalia, Hawaii. The invention belongs to that class of anchors in which a number of flukes are carried on a yoke frame and have a limited rotary movement relative thereto to engage in the mud or sand. It has in view an anchor in which the flukes are detachably connected and may be increased and decreased in number so that the anchor may offer the requisite resistance.

JIG.—W. A. BRADLEY, Spokane, Wash. The invention provides a device for rapidly and thoroughly separating the values from crushed ores, by means of which the gangue or tailings can be reconcentrated and which provides efficient means for forcing water or other liquid rapidly back and forth through a screen, to assist in the separation of the material.

REVERBERATORY SOUND-HORN.—W. A. CHAPMAN, Smithville, Ark. The invention enables the manufacture of sound amplifiers as used with talking machines, at a reduced cost; provides for increasing the artistic attractions of the reeds through action of light, [illegible] in line of the horn [illegible] [illegible] resonant and in a natural manner, prevent mingling of sounds with those external, and affords a self-contained and perfectly balanced amplifying horn for sound reproducing machines.

DENTAL CUSPIDOR.—I. M. HAIR, Union, S. C. An object here is to provide a portable cuspidor which may be flushed by a stream of water operated by compressed air. A further object is to provide a device in which the flushing operation may be performed through the instrumentality of a foot lever attached to the device, thereby permitting the dentist to use both hands in other work.

FISH NET.—D. P. GILSTRAP, Brownwood, Texas. The intention in this instance is to provide a woven net formed of intermeshed cords without floats, sinkers, drawstrings and the like encumbering attachments, and which will run freely upon a single supporting cord. A further intention is the provision of an improved spring trip for the cord. It acts as an animal trap as well as a net.

STAIR.—J. C. TOLIVER, Ainsworth, Neb. The stairs are of that class in which a chute or wheelway is provided on each side of the steps constituting the stair proper. The invention consists in the construction and arrangement of the chute on the sides of the stairs proper, whereby dust, dirt, or other material that may accumulate upon the stairs may be swept or pushed directly off of the same into the chute.

BOAT.—H. W. VANIMAN, Cincinnati, Ohio. The purpose of the inventor is to provide a non-sinkable and non-oxidizable boat comprising a plurality of sections, sundry preferably two of which are of greater size for the center and capable of receiving the other sections therein in nested relation, the said larger sections being then secured together.

BAG HOLDER.—B. BOAH, Kennedy, N. Y. Among the principal objects which the present invention has in view are to provide a bag holder to hold the opening or top of a bag square and in an inclined position; to provide a holder for a bag which will yield to the variation in length caused by the filling of the bag; and to provide a structure which is light, simple, and efficient.

STOPPER RETAINER.—A. C. BOOMS, Jr., Fort Dodge, Iowa. The aim in this case is to provide a spout or stopper retainer for oil cans, which can be applied to cans of various types, which can be secured to the spout of the can after the can is finished which does not interfere with the flow of heavy oil through the spout and which does not interfere with the introduction of oil into the can.

PYROGRAPHIC POINT.—L. QUOSSANTH, Newark, N. J. This invention pertains to improvements in the construction of tools or points of pyrographic burners, thermocauters and cauterizing tools, and to the means for securing the tip or point in place. The main object of the inventor is to so form the tip and the securing means therefor that the tip cannot work loose in use, but may be instantly and easily removed when desired to replace or repair.

### Heating and Lighting.

LAMP.—W. S. RYAN, Viola, Ill. The present invention not only has in contemplation the location of the supply reservoir in the lamp post or casing, but also the feed tank which supplies the fuel to the lamp, together with means for introducing fluid pressure above the free surface of the fuel in both the reservoir and feed tank, to respectively discharge the fuel in the reservoir to the feed tank above and thence feed the fuel under the pressure to the lamp.

BAKING STOVE.—J. A. COPPRIDGE, Browns Summit, N. C. This invention is an improvement in baking stoves, being especially designed as a stove for use in baking bread, and has for an object to provide a simple construction which will be efficient for the purpose, can be easily taken apart and stored in compact form so it will be convenient for camping purposes.

### Machines and Mechanical Devices.

MEANS FOR THE PROPULSION OF VESSELS.—R. P. NIELSEN, Tranebjerg, Samsö, Denmark. The improvement relates to the propulsion of vessels and has for its object to provide a cheap and effective propelling mechanism. The pairs of chains being set in motion the vessel is propelled and owing to the inclination of the plates of the blades, they tend to raise the vessel and thereby facilitate its passage through the water.

AUTOMATIC PHOTOGRAPHIC PRINTING MACHINE.—G. W. FERGUSON, Plymouth, Wis. The aim of this inventor is to provide means for rapidly printing photographs from negatives by giving each photograph the same time limit of exposure, by means of an automatic arrangement, which makes each photograph exactly the same. By this method photographs may be printed whenever desired without the aid of sunlight as in the old method.

DISPLAY-MACHINE.—J. S. ANDERSON, Newport, Ky. Among the principal objects which the invention has in view are to provide a sign in which the exposed matter is continuously changing, and in which the change, [illegible] dissolving view; to provide a driving mechanism which is positive and smooth in its operation, and to provide a mechanism whereby the display members are brought together to present a continuous surface.

BURGLAR ALARM.—W. G. TILLMAN, New York, N. Y. This alarm is more especially designed for use in connection with doors so that when the door is opened by a burglar or other unauthorized person, then the alarm mechanism is actuated to sound a bell, and when the door is returned to closed position the sounding of the bell is temporarily continued.

WIRE-NETTING WEAVING MACHINE.—C. E. BACH, Mosman, Sydney, New South Wales, Australia. In the present patent the invention has reference to certain improvements in wire-netting weaving machines and its purpose is to dispense with the tube cones and the connections at present used and consequently with the necessity for the special coiling.

JOINTED FIGURE.—G. W. FERGUSON, Plymouth, Wis. This figure may be of wood or other material, and the construction adapts it to receive many adjustments of its head and all other members, thus rendering the mechanical simulation of a human animal, fowl or reptile figure, grotesque and very amusing.

TYPE WRITING MACHINE.—W. C. PAUL, New York, N. Y. The purpose here is to provide an improvement particularly of the wheel class of machines, or class wherein a wheel is mounted to turn upon a spindle, and to provide means for automatically operating a type wheel to the various printing positions corresponding to the keys depressed, and for automatically locking the wheel in position during the operation of printing.

CENTRIFUGAL MACHINE.—F. ROBERTS and A. H. GIBSON, Lehi, Utah. To empty the sugar, the machine is slowed up somewhat and the hollow shaft being elevated the bracket is swung so that the horizontal portion thereof projects over the casing. The hand wheel is now turned to lower the hollow shaft through an opening in the top of the casing, after which the lever is turned to bring the paddle into position. After the sugar is loosened the lever is operated to swing the paddle into position and the hand wheel is rotated to elevate the paddle from the casing after which the side of the bracket may be swung to the side of the casing out of the way.

COPY HOLDER.—H. F. PERTZ, Moro, Ore. The main object in this patent is to provide a holder which will bring the lines of the copy into view of the operator consecutively as the platen is rotated for line spacing. A further object is to provide means for operating the holder so that it will feed the copy faster or slower and in such a manner as to be entirely independent of the rotation of the platen.

### Prime Movers and Their Accessories.

INTERNAL-COMBUSTION ENGINE.—P. DANIEL, New York, N. Y. In the present patent the invention relates to certain improvements in 2-cycle internal combustion engines, and relates more particularly to the means employed for supplying the fuel to form the explosive mixture and for automatically controlling the amount of fuel admitted.

OIL-PROOF SPARK PLUG.—F. J. BUSBY, New York, N. Y. The improvement relates to internal combustion engines and its object is to provide a spark plug arranged to prevent oil or the like splashed up against the plug from passing into the spark gap or into the interior of the plug thus protecting the cup against deleterious influences of the oil and keeping the plug at all times in effective condition.

ROTARY INTERNAL COMBUSTION ENGINE.—J. S. STEWART, Diamondville, Wyo. In this instance the intention of the inventor is to provide an improved rotary internal combustion engine which is simple and durable in construction composed of comparatively few parts, and not likely to get out of order, and arranged to utilize the motive agent to the fullest advantage.

### Railways and Their Accessories.

RAIL-FASTENER.—O. ASHWORTH, Wappingers Falls, N. Y. This improvement refers to fasteners for securing railroad rails upon cross ties, and relates more particularly to a device comprising a chair adapted to carry a rail and to rest upon a tie, a holding member extending from the chair to the under part of the tie, and means for securing the member at the under part of the tie.

### Pertaining to Vehicles.

VEHICLE-BRAKE.—V. T. SWEANEY, Anchorage, Ky. An object here is to provide a brake having means to manually operate the brake and control the same and also to provide means connected with the brake whereby the same may be automatically operated by the action of the team attached to the vehicle in backing, the manually-controlled means and the automatic means being independently operative to apply or release the brake.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## NEW BOOKS, ETC.

ORNAMENTAL CONCRETE WITHOUT MOLDS. By A. A. Houghton. New York: Norman W. Henley Publishing Company, 1910. 16mo., 182 pp. Price, $2.

This book treats of the forming of concrete objects in cement by the means of templates. This method is not new, as it involves practically the same methods as used for years in running plaster moldings, outer pieces, etc. It has also been explained in detail in "Concrete Pottery and Garden Furniture," by Ralph C. Davison, published by Munn & Co. The use of templates in concrete work is good for certain classes of work but the field is limited, inasmuch as plain surfaces only can be produced; that is, no bas relief work can be reproduced, such as is possible with either glue or plaster molds. This work contains 124 pages, including 30 full page line drawings and 20 chapters, many of which are only from one to three pages in length. Several of these chapters are superfluous inasmuch as they only repeat dimensions which are clearly shown in the illustrations. The larger portion of the work treats of the various architectural orders rather than of how to produce concrete ornaments. If as much space was devoted to the proper ingredients to use in the concrete mixture and the proper proportions to use in same, as well as to the all important question of curing the casts—points which have not been touched on at all—the work would be of more practical use to those for whom, the author states, it is intended, as there are very few who understand the great importance of the proper mixtures to use or the time and methods to be used for producing a perfectly cured cast. The proofreading could be improved on; also the index is not above reproach, as for example the reference to Crazing, page 23. The circular states "The process of making ornamental concrete without molds has long been a secret and is now given for the first time in this practical book." This statement is misleading and not warranted by the facts. There is no secret about this process.

MODERN PAINTER'S CYCLOPEDIA. By F. Maire. Chicago: Frederick J. Drake & Co., 1910. 16mo., 465 pp.

Among the subjects treated are: Adulteration of Paint, Blistering of Paint, Brushes, Calcimining, Carriage Painting, China Painting, Colors, Color Harmony, Color Mixing, Color Testing, Exterior Painting, Frescoing, Gilding, Graining, House Painting, Marbling, Oils and Driers, Oil Painting on Glass, Painting a Bath Tub, Painting in Distemper, Paperhanger's Tools, Paper hanging, Pigments, Sash Painting, Sign Painting, Stains, Staining, Stenciling, Statuary Painting, Turpentine, Varnishes, Varnishing, Water Color Painting, etc.

**The Latest Giant Freight Engine.**

(*Concluded from page 436.*)

miles. On these divisions there is a heavy movement of freight traffic, consisting mostly of loaded coal trains. The grade conditions on this portion of the road are severe and sharp, curves are numerous. Against northbound traffic in which direction practically all the movement of loaded freight trains takes place, there is a six mile grade of 1 36 per cent from Carbondale to Forest City. From the latter point to Ararat, the summit of the rise, a distance of 14 miles the road is on a grade averaging 0 81 per cent. Going down the other side of the mountain, it is practically a continuous grade of 51 7 feet per mile for 77 miles into Oneonta.

Hitherto the freight traffic on this division has been handled by consolidation locomotives, having a theoretical maximum tractive power of 49,690 pounds. A single engine of this class can very satisfactorily handle a 2 600-ton train from Ararat to Oneonta, but it requires the assistance of two locomotives of the same class, as pushers, to haul this load up the 20-mile grade to Ararat, at which point the pushers cut loose.

With a view to reducing the operating expenses of the division and facilitating the movement of trains, the officials of the Delaware & Hudson Company decided to investigate the efficiency of the Mallet type locomotives for this service. It was their aim to secure a pusher engine of this type of sufficient power to move the maximum train load up the hill with two engines instead of three.

In the fall of last year one of the heavy Mallet engines built by the American Locomotive Company for the Erie Railroad was borrowed, and put into pusher service on the 20-mile Ararat grade. A number of test runs were made which proved that a single Erie Mallet engine easily did the work of two of their Class E-5 consolidation locomotives. Following these tests the six Mallet engines were ordered from the American Locomotive Company, and put into this service.

These engines are of a straightforward design, embodying but slight modifications from the designs of previous locomotives of this type of lesser weight and power constructed by these builders. With the boiler pressure of 220 pounds and driving wheels 51 inches in diameter, the theoretical maximum tractive power working compound calculated by the company's formula is 105 000 pounds.

As this formula which is applicable only to articulated locomotives built by this company, is based on the results obtained from a large number of indicator cars, taken under various service conditions, it is found that the tractive power thus calculated represents very accurately the actual power that the locomotive can develop at a piston speed of not over 250 feet per minute.

With the company's system of compounding the normal maximum tractive power working compound, can be increased about 20 per cent by changing the engine into simple. The maximum tractive power of these engines working simple is thus 126 000 pounds.

**New Two-Cycle Motors.**

(*Continued from page 444.*)

compressed air which would then be furnished by chamber *B* to receiver *D*. It is well understood that the high velocity produced by air under pressure is far more efficient in atomizing liquids than the comparatively low velocity produced by suction. This type of engine should produce twice the power of a four-cycle engine of the same size and speed, and we are informed that tests now being made show this to be the case.

Another engine using a differential piston but in an entirely different way is the Shortt Motor. This engine compresses air only in the crank case. Unlike the others here described it does not admit this air through a port opened

(*Concluded on page 450.*)

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The Nat'l Co-op. Real Estate Co., Suite 378, Marden Building, Washington, D. C.

Inquiry No. 9018.—For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

FIFTY DOLLARS AND UP weekly made by any live hustling agent selling Thurman Vacuum Cleaners, "The standard of the world." Not toys but machines of the highest grade. Every sale means "an agent working for you." You can build up a permanent, paying business. Write for agency proposition. Gen'l Compressed Air & Vacuum Mach'y Co., 546 N. Taylor Ave., St. Louis, Mo.

Inquiry No. 9087.—Wanted the manufacturers of the Van Winkle, Woods & Sons, and the Weber power meters.

## HELP WANTED

GET A BETTER PLACE.—Uncle Sam is best employer; pay is high and sure; hours short; places permanent; promotions regular; vacations with pay; thousands of vacancies every month; all kinds of pleasant work everywhere; no lay offs; no pull needed; common education sufficient; find out how you can have a position guaranteed you by asking today for R. R. 40. Free. Earl Hopkins, Washington, D. C.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## FOR SALE

FOR SALE.—Interest or control in manufacturing business. Exceptional opportunity for manager or instrument maker. Control, Box 773, N. Y.

Inquiry No. 9019.—Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

WILLIAMS-EARLE alcohol radiant projector lantern, with 12 mantles, cost $78.40, price $35.00; 67 astronomical slides with carrying case for 30 cost $34.75, price $17. For sale separately or whole outfit $40, all absolutely new. 105 Wall St. Room 45, Phone 1548 John.

Inquiry No. 9023.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

## PATENTS FOR SALE

PATENT No. 935,620. An improved vehicle wheel, intended for automobile, or to take the place of pneumatic tires. John H. Scott, 63 Prince St., New York City.

Inquiry No. 9029.—Wanted catalogues and all information on machinery for braiding straw to manufacturing straw hats.

MUST SELL PATENT (951,377). Recording Target Army, National Guard, shooting clubs, colleges, police, etc. Mfd. U. S. $100.00 profit each. Great hit. Particulars J. J. Metzner, Public Square, Cleveland, O.

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

THERMOS BOTTLE REFRIGERATOR. Pat. March 1st, 1910, No. 951,038 covers the idea broadly of a refrigerator each of whose sides is cast in one piece of glass, porcelain or aluminum (porcelain covered), and hermetically sealed to form independent vacuum chambers on the nature of the Thermos bottle. Royalty preferred. A. K. Cross, 8 Beacon Street, Room 35, Boston, Mass.

Inquiry No. 9060.—Wanted to buy machinery to manufacture seed corn racks.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9075.—Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

## SALE AND EXCHANGE

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $45.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9077.—Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

## MISCELLANEOUS.

STAR Sphere of Light Clock. For particulars address William Rose.

Inquiry No. 9078.—Wanted the address of manufacturers of sewer pipe made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9083.—Wanted, the address of firms manufacturing small beer brewing plants, from 15 to 20 gallons a day.

Inquiry No. 9092.—Wanted the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9091.—Wanted address of The Thomas Arithmometer Company, also Burkhart Arithmometer Company.

Inquiry No. 9096.—Wanted the address of manufacturers of spiral welded pipes possessing great strength.

Inquiry No. 9097.—Wanted address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted name and address of the manufacturers of the oscillator.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9101.—Wanted, addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9107.—Wanted, addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9112.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114.—Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9116.—Wanted a machine for making pen nibs, similar to Wm. Mitchell's J. & J. nibs and Waverly nibs.

Inquiry No. 9117.—Wanted names and addresses of the manufacturers of pedometers.

Inquiry No. 9118.—Wanted, a muffler for a gasoline engine, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9119.—Wanted, name and address of the manufacturer of Berlin bullet-proof cloth.

Inquiry No. 9120.—Wanted, the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted, manufacturers of cut stencils for fancy work, sofa pillows, etc., and oil colors and brushes for same.

Inquiry No. 9124.—Wanted, name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9127.—Wanted, address of L. Dermigny, manufacturer of a family ice machine for $25.00.

Inquiry No. 9123.—Wanted, manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots, used in making oil of sassafras.

Inquiry No. 9124.—Wanted, a small hydraulic motor, capable of giving about one horse power with a water power of 35 lbs. per square inch.

Inquiry No. 9125.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9126.—Wanted the name and address of a skunk raising farm.

Inquiry No. 9127.—Wanted, a device that will braid leather strips for horse whips.

Inquiry No. 9128.—Wanted, the address of manufacturers of machines capable of forming a number (11 or more) of pieces of paste about 50 mm. x 25 mm. x 6 mm., made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139.—Wanted, the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted, manufacturers of disc records for gramophones that use a sapphire point instead of a steel needle.

Inquiry No. 9143.—Wanted name and address of the manufacturers of an air mattress.

Inquiry No. 9144.—Wanted, manufacturers of machinery for making soda water tubes, commonly known as straws.

Inquiry No. 9145.—Wanted to buy machinery to load blasting caps or detonators.

Inquiry No. 9149.—Wanted, manufacturers of machinery for roasting coffee for small and large industries.

Inquiry No. 9150.—Wanted, manufacturers of machinery for the manufacture of French heels for ladies' shoes.

Inquiry No. 9152.—Wanted, the address of the Graham Safety Lamp Filler and Ventilator.

Inquiry No. 9153.—Wanted, name and address of manufacturers of a knotless clothes line.

Inquiry No. 9154.—Wanted name and manufacturers of a newspaper vending machine.

Inquiry No. 9155.—Wanted, the address of manufacturers of an electric milking machine.

Inquiry No. 9156.—Wanted the name and address of manufacturers of a rust proof oil, known as Caoutchouc Oil.

Inquiry No. 9157.—Wanted, manufacturers of peanut shelling and cleaning machinery.

Inquiry No. 9158.—Wanted, manufacturers of a material in sheets to take the place of vulcanized fibre for novelty work.

Inquiry No. 9159.—Wanted, manufacturers of any successful substitute for hard rubber.

Inquiry No. 9161.—Wanted, a machine that will grind oranges, pulp and skin into a smooth liquid or cream.

Inquiry No. 9162.—Wanted, addresses of shirt makers in Manhattan, who will make a few shirts of special design.

Inquiry No. 9163.—Wanted, manufacturers of a cradle worked by clock work.

(Concluded from page 440.)

by the piston, but uses instead a valve which is vacuum actuated. The partial vacuum to operate this valve is formed above the larger differential piston $F$. When this piston reaches the bottom of its stroke it uncovers a port $G$, through which air enters and breaks the vacuum, whereupon the valve instantly closes. The fuel is fed from a pressure tank through a needle valve, and is delivered at the seat of the main inlet valve. As the pressure in this tank is greater than that of the inrushing air from the crank case, it forces the fuel into the cylinder against the air pressure. It is claimed that the time the valve is open will vary with the speed of the engine so as to let in the right amount of fuel. The annular chamber of the piston is used only to produce a partial vacuum which operates the main valve. This engine should get sufficient air for clearing the cylinder on account of the enlarged piston end and should be able to produce considerably more power than the usual two-cycle motor.

Prof. S. P. Thomas recently stated before the Royal Society that he had succeeded in producing a physiological effect by means of magnetism. A coil of copper wire was made 9 inches in diameter and 8 inches long, containing 32 turns. Through this an alternating current of 50 cycles was passed, with a maximum flow of 180 amperes, giving 5,760 ampere turns. In a dark room, when an observer placed his head in the mouth of the coil, he could see a faint bluish light, which was not steady but appeared to flicker considerably. This could be observed

[illegible] with the eyes closed. When the experiment was tried in broad daylight with the eyes open, this flickering sensation still persisted. The blue light, which was visible only in the dark, appeared to be brighter near the wire than in the center.

### How to Act in Case of Fire.

(*Concluded from page 441*)

dredging the part thickly with flour—if the skin is not broken—and not disturbing it for some time.

Any vegetable oil—such as salad, sweet, or linseed—may be used with advantage, a rag being soaked with it and used to cover the wound. A very good application is made by mixing equal parts of linseed oil and lime water, forming "carron oil."

Finally, it cannot be too strongly impressed that all clothing covering a burn must be removed with the utmost care. Never try to withdraw the injured limb, but cut the clothing away—in small pieces, if necessary—so that the injured surface may not be more damaged. Never hold a burn in front of the fire, according to the popular practice, this only increases the injury. Have your oil or other application ready for immediate use as soon as the clothing has been removed.

### Fontenelle's Theory of Comets.

The idea of comparing comets to great glass lenses, which concentrate the sun's rays into luminous cones which appear as the comets' tails, is so natural that its origin cannot be traced. It was indicated by the philosopher Seneca, about the commencement of the Christian era, but it has been abandoned in accordance with the example of Kepler, who after first embracing this doctrine with enthusiasm, renounced it on discovering that a large comet, which he had occasion to observe, possessed a curved tail. The impossibility of explaining this phenomenon, at a time when it was not known that light consumes a measurable time in traversing interplanetary space, caused Kepler to abandon the idea. The celebrated Fontenelle, regardless of this objection, took up and expounded the lenticular theory of comets in an admirable manner in his "Plurality of Worlds." The coming of Halley's and several other comets has caused Wilfrid de Fonvielle to recall the attention of the French Academy to Fontenelle's theory and the arguments which may be brought forward in its favor. At present, on the coast of every civilized country, phenomena similar to those to which Fontenelle attributed the formation of the tails of comets, are produced by the lanterns of lighthouses. The dust which is suspended in the atmosphere is illuminated by the beam of light as Fontenelle supposed the cosmical dust to be illuminated by the concentrated beam of sunlight behind the lenticular comet. De Fonvielle shows that this theory explains the individual peculiarities of comets, and is confirmed by observations made recently at the Paris and Greenwich observatories. For example, a division of the tail is explained by assuming that the cloud of cosmical dust is not continuous, but intermittent, and the occasional sudden appearance of bright points indicates the existence of a reflecting body of considerable size. In a word, all the variations which are observed in meteoric showers might on this theory be expected to occur in the tails of comets. The evidence of the spectroscope and the freaks of Morehouse's and Halley's comets are against this lenticular theory.

Engineers of the United States Geological Survey estimate the annual damage by floods in the United States at $100,000,000. It is too early, perhaps, to undertake to prevent or to diminish this immense loss, but its very magnitude invites a serious study of means of prevention, and the recent misfortune of France may lead to practical work that will serve as an object lesson to America.

## HALLEY AND HIS COMET

**The year 1910 is destined to be one of the most famous in astronomical history, simply because Halley's comet has returned after a lapse of seventy five years. Why not learn all about this wonderful comet and about comets in general by reading the following articles?**

Scientific American No 19, Vol XCVIII **Gas Phosphorescence and Meteor Trains.** An article in which the investigations of C C Trowbridge of Columbia University are described showing that the after-glow produced from a vacuum tube resembles closely the effect produced in the sky by the passage of meteors

Scientific American No 6 Vol XCIX **The Mystery of Comets.** An article in which the famous comets of the last century are enumerated and described and modern cometary theories discussed

Scientific American Supplement No. 1728 **Ancient and Popular Ideas About Comets.** Queer superstitions about the strangest of heavenly bodies

Scientific American No. 7, Vol CI **Halley's Comet** An interesting article by Dr Alexander W Roberts, in which the general history of Halley's famous comet is sketched with comments on its past appearances

Scientific American Supplement No 1705 **The Next Apparition (1910) of Halley's Comet.** An important article by H C Wilson, with a map giving the position of the comet relatively to the orbits of the planets from September 15 1908, to July 13, 1910.

Scientific American Supplement No 1632. **Halley's Comet.** An article by I W Henkel, F R A S, which tells how Halley came to discover the comet which bears his name, and how mathematicians have plotted its orbit

Scientific American Supplement No 1770 **Edmund Halley.** A biography by J E. Gore, M R I A, of the man who dispelled cometary superstitions and popularized the law of gravitation

Scientific American Supplement No 1773. **Light Pressure and Comets' Tails** An explanation of the vagaries of a comet's tail, by Arthur Stanley Eddington, F R A S

Scientific American Supplement Nos 1788 and 1789. **Halley's Comet.** By George F Chambers F R A S The most thorough article which has thus far appeared on Halley and Halley's comet

Scientific American No 13, Volume CII **Condensed Facts About Halley's Comet.** By H W. Griggs A few facts presented in condensed form for those who wish to follow the course of Halley's comet in the heavens. Maps showing the apparent path of Halley's comet through the heavens and the relation of the orbits of Halley's comet and the planets

Scientific American No 16, Volume CII **Halley's Comet at its Brightest** By Professor Henry Norris Russell A simply worded astronomical article telling how Halley's comet was discovered on its present return when it will appear at its brightest, where to look for it, what it is composed of, etc

Scientific American No 18, Volume CII **How to Make a Model of the Orbit of Halley's Comet, Showing its Relative Position to the Earth's Orbit.** Designed by James K. Lynch By means of this model many of the phenomena of Halley's comet can be explained

Scientific American Supplement No 1772 **Photographing Comets.** By E E Barnard, of Yerkes Observatory A practical article on how to photograph Halley's comet

Scientific American Supplement No. 1778. **Halley's Comet.** An article in which the suggested observations proposed by the Astronomical and Physical Society of America are given, so far as photography and spectroscopic observations are concerned.

Scientific American Supplement No 1782 **Halley's Cometary Studies.** Halley's own account of his investigations on orbits.

Scientific American Supplement No 1785. **Halley's Comet as Seen from the Earth.** A table prepared by the distinguished Greenwich astronomer, P H Cowell, giving the ecliptic co-ordinates of Halley's comet to two decimal places at intervals of four days through an arc extending from one end to the other of the latus rectum of its orbit. The figures apply approximately to any return.

Scientific American No. 10, Vol CII **Could the Earth Collide with a Comet?** An examination of past comet scares and the general possibility of collision of a comet with the earth.

Any one of these papers will be mailed on receipt of 10 cents. The entire set will be sent for $1.70. Order from your newsdealer or from

**MUNN & COMPANY, Inc., 361 Broadway, New York City**

Notice of a fire comes to the operator at telephone (see view of pumping station), who instructs engine room crew by means of marine telegraph. The engineer at switchboard starts electric pumps which draw water from the water mains or the river, and deliver it through mains to the district in which fire rages. The chief at the fire is in touch with station operator through special telephone wire.

NEW YORK, SATURDAY, JUNE 11th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

### WHAT WILL THE RAISING OF THE "MAINE" DISCLOSE?

THE action of Congress in passing a bill making a preliminary appropriation for the work of raising the wreck of the "Maine" is, for several reasons, highly commendable. Chief among these is the opportunity which will be afforded to give decent burial in the national cemetery at Arlington to the bodies of the unfortunate men who were carried down in the wreck of the ship, and have remained entombed for the past twelve years. Look at it whatever way we will, the fact that no effort has been made to recover these bodies carries with it a certain uncomfortable aspect of neglect, and the nation owes it to the memory of the dead, to the sensibilities of their surviving relatives, and lastly to its own dignity and self-respect, to recover what may be left of the mortal part of these brave seamen, and give them decent interment with proper military honors.

Second only in importance to the above considerations are those which affect the sensibilities, and particularly the sense of honor, of a European power with whom we are at present and hope ever to be, on terms of friendly understanding; for it is a fact that the Spanish government felt very keenly the implication that the destruction of the "Maine" was brought about by Spanish agency—an implication which, though not expressed, yet necessarily followed from the finding of our Naval Board of Inquiry, which concluded that the "Maine" was destroyed not from within, but from without. "In the opinion of the Court," says the report, "this effect could have been produced only by the explosion of a mine situated under the bottom of the ship at about frame 18 and somewhat on the port side of the ship."

Now, although our Navy Department did not then and does not now, believe that the Spanish officials were in any way concerned in the disaster, attributing the explosion to the hatred of fanatics, it is doubtful if this opinion was shared, or is even yet held, by the majority of people in the United States. Therefore the raising of the "Maine" will be well worth all the trouble and cost it will entail, if the thorough physical examination of the wreck which can then be made, brings to light clear evidence that the explosion was due to internal causes, that is to say, to the spontaneous and therefore accidental combustion of the explosives contained in the forward magazines. This latter was the explanation offered by the Spanish Naval Board which examined the wreck at the time of the disaster, and it is significant that it received credence not only among naval experts abroad, and especially those of England, whose attitude was markedly friendly at the time, but also among not a small percentage of the officers of our own navy.

It would be a "consummation devoutly to be wished" if the raising of the wreck should afford ample evidence or even a strong presumption, that the "Maine" was wrecked by spontaneous explosion in the magazines. Such a conclusion would cast no discredit whatever upon the officers and men who had charge of the "Maine" on that fatal night, for it is well understood and has been proved by accidents such as that which occurred on the French battleship "Jena," that under the conditions in which powder was stored at that period and for some years later it was possible for spontaneous combustion to have taken place in spite of that strict observance of regulations, which the evidence before the Board showed to have been followed on the "Maine."

Now, if this occurred, the tearing asunder of the protective deck and the blowing out of the sides of the vessel, accompanied by the instant flooding of the portion of the ship forward of the explosion, would have caused the weight of the ram bow, the anchors and anchor chains, to bend the forward portion downward until the ram was hanging vertically below the ship, held thereto only by the floor and keel plates. Then, as the main portion of the ship filled and sank, the bottom of the ship would naturally be folded down vertically against itself, leaving the keel and the double bottom in that peculiar, inverted V position, which gives it the appearance of having been blown up by some powerful force acting from below.

When the cofferdam has been built entirely around the wreck and the water pumped out, it will be possible, in all probability, by a careful examination of the wrecked structure, to determine how far this theory is correct. If it be proved there will be cause for general congratulation. With that awful tragedy transferred to the category of unpreventable accidents, a proud nation with whom we are in friendly relationship will be vindicated from a charge which even today is a source of resentment that is none the less real because it is unexpressed.

### REVIVAL OF THE ROTARY ENGINE.

IN the introductory article of a series dealing with the rotary engine which was published in the year 1897 in the SCIENTIFIC AMERICAN (Vol. lxxvii, Nos. 1109, 1110, 1111), we said: "The constant failure that has attended the efforts to produce a successful rotary engine, and the fact that the direct-acting crank and rod, reciprocating engine has retained full possession of the field, have led many people to suppose that the rotary engine inventor is as visionary a dreamer as the would-be inventor of perpetual motion. As a matter of fact, however, many of the objects aimed at in the first device are as legitimate and useful as those of the latter are absurd and impossible. While the supposed advantages of a rotary engine as outlined below, have proved very attractive to the inventor, the results of careful comparative tests have shown that except in the case of rotary impact engines or steam turbines, the rotary engine does not compare in efficiency with the ordinary reciprocating type. . . . Now it would certainly seem that with such theoretical and practical mechanical features in its favor, the rotary engine would prove a formidable rival to the standard type. But this it has never done, and for the very practical reason that owing to its peculiarities of construction, it is difficult to secure an economical regulation of the steam supply, and it is impossible to keep the joints steam tight and prevent irregular wear of the parts. The wear of the piston is always greatest at the circumference of the cylinder, decreasing toward the center, and this structural defect has thus far baffled the efforts of the mechanic. The packing devices that bear against the circumference of the cylinder, like the piston rings of a vertical direct-acting engine, show an equal wear throughout; but no amount of ingenuity has yet succeeded in compensating the variable wear of the side packing. There is a further difficulty in the fact that in rotary engines that have only one admission port the steam pressure produces a rapid side wear on the shaft, and renders it difficult to keep the stuffing box steam tight. Another difficulty is experienced with the valve gear, which in the great majority of rotary engines is of the reciprocating type. Reciprocations which would involve no serious wear at a moderate speed become serious at the enormous speed of the rotary engine, and produce rapid wear of the parts."

Such was the situation in the rotary engine field about a dozen years ago. The difficulties were of a purely mechanical kind, for the theoretical advantages of the type were highly attractive and never disputed. We remember asking the late George M. Hopkins, a mechanical engineer of exceptional constructive ability, who had devoted a large amount of effort to the problem, what he thought were the prospects for the production of a successful motor of this type. He expressed the opinion that the large steam leakage, due to the impossibility of making successful frictional joints coupled with the heavy frictional losses, to say nothing of the rapid wearing out of the reciprocating valve movements had convinced him that no successful rotary could be built.

As the matter then stood, it was evident that a rotary engine, to be successful must be absolutely rotary in all its parts and free from any reciprocating movements whatsoever, that the rubbing surfaces must be reduced to a minimum, if not altogether eliminated, that steam leakage must be greatly reduced; and that some mechanical means must be found for eliminating the uneven wear on the main bearings due to the eccentric application of the load. In the intervening years, in spite of apparently insuperable difficulties, inventors have struggled with the problem with that indomitable perseverance which is so frequently characteristic of their work, with the result that at last a rotary engine of twenty horse-power has been developed, which has shown its ability to perform steady shop duty, day in and day out, for a period of months, without showing any signs of deterioration. Reference is made here to the exceedingly interesting engine, recently tested at Stevens Institute, which forms the subject of an illustrated article on another page. It will be recognized, on a study of the drawings and description, that success has been achieved by meeting those very conditions of a mechanical nature, which the experimental work of the past hundred years had shown to be essential in a rotary engine. The tests at Stevens Institute and at the contractors' plant speak for themselves. It remains for the future to determine how far the rotary will succeed in the new field of high-pressure, superheated steam, for which, theoretically, it would seem to be admirably adapted.

### THE GOVERNMENT AND THE INVENTOR.

THE Committee on Patents has under consideration a bill introduced by Mr. Currier, the purpose of which is to enlarge the jurisdiction of the Court of Claims so that the Court may entertain suits against the United States for the infringement or unauthorized use of a patented invention in certain cases, and award reasonable compensation to the patentee.

The measure is necessary, when it is considered that under the English common law, which prevails in this country as well as in England, a sovereign power cannot be sued without its own consent. The United States has established a regular tribunal, and charged it with the duty of adjusting claims against the government; but the scope of its duties does not include the adjudication of an inventor's rights when his invention has been appropriated by his government.

When the government issues a patent, it does not grant a favor to the inventor, but it "secures him a right," in the language of the Court in U. S. vs. Palmer (128 U. S. 271), and this securing of a right by no possible implication carries with it the opposite power of destroying the right in whole or in part by appropriating it to the purposes of government without complying with that other condition of the Constitution, the making of "just compensation."

For all that many inventors have spent years of their lives and practically bankrupted themselves in developing inventions primarily of use to the government only to find in the end that their property has been practically confiscated; that they have no legal means of redress, and that the governmental departments will not recognize the decisions of the courts. No doubt the government has the right to appropriate an invention necessary for the preservation of the national defense; yet appropriation having been made, it would seem that some compensation should be paid.

Despite the decisions of the Supreme Court, despite the fifth amendment to the Constitution, which provides that no private property shall be taken for public use without compensation, the government again and again seizes private property, in the form of patent rights, without compensation. The Court of Claims now has no jurisdiction to award compensation for the governmental use of a patent, except when such use is under a contract. To extend the jurisdiction of the Court so that it may entertain suits and award compensation to the owners of patents in cases where the use of the invention by the United States government is unauthorized, is the purpose of Mr. Currier's bill.

A similar measure was introduced by Congressman Dalzell in the closing days of the last Congress. The measure passed both the House and the Senate, but it was not signed by the President. Mr. Currier's bill is practically the same as Mr. Dalzell's with the exception that certain patents taken out by government officers or employees, which are good against all the world, are not good against the government. This is as it should be; for when a government officer is assigned to the task of devising an implement, and the government bears the expense incidental to the invention, and the officer continues to draw his salary in the meantime, it is evident that the government is the implied owner or at least licensee of the invention.

The experimental researches into the effect of electricity upon fog commenced by Sir Oliver Lodge in Liverpool, and continued by him in Birmingham, have been temporarily suspended. The reason for this, the Electrical Engineer states, is not any modification of Sir Oliver's views on the subject, or any cessation of his interest. It is simply that the spot selected for the experiments in the neighborhood of the old university buildings in Edmund Street has failed to furnish the *corpus vile* in the shape of fogs to disperse. There is a proposal to conduct a similar experiment under Sir Oliver Lodge's direction and on a more extensive scale in London, somewhere in the neighborhood of Hungerford Bridge, where it is hoped a choice assortment of fogs may be more often available. A sum of about $5,000, however, is required in order to enable this installation to be made, and at present it is not clear how the funds are to be obtained.

## ENGINEERING.

It is claimed by the contractors that a new record for American shaft sinking has been accomplished on the Moodna siphon of the New York city Catskill aqueduct, where a shaft 16 feet 8 inches in diameter was sunk 177 feet in thirty-one days. The work was done in hard Hudson River shale.

In a recent government test over the measured mile course off Rockland, the new battleship "Michigan" covered the fastest mile out of twenty successive runs at a speed of 19.54 knots, which exceeds by more than half a knot the fastest mile made at the builders' acceptance standardization trial.

The first of three concrete barges which will be used in the hydraulic operation at the Panama Canal was recently launched. It draws when complete with dredging pump, motor, and equipment, three feet nine inches. One-quarter-inch No. 12 wire mesh has been used in the wall construction. The behavior of these barges will be watched with great interest.

The Interstate Commerce Commission has recently ruled that, hereafter, on several railways in the Northwest, the upper berths in Pullman sleeping cars are to cost less than the lower berths. The Commission states that, in the past eleven years, the Pullman company has doubled its capitalization and dividends without the investment of any new capital.

The latest report of work on the New York State barge canal shows that this great undertaking is being pushed through with dispatch. At the present time, 332.6 miles of the total work is under contract, additional plans have been completed for 48.2 miles, and the plans for another 26.4 miles are over seventy-five per cent completed, leaving 6.4 miles, the plans of which are in progress.

With a view to determining whether or not the new type of shells will be deflected when striking at an angle, or whether they will bite into the plate, several of the new soft nosed naval shells were fired from a 12-inch gun at the old ram "Katahdin," which was stricken from the navy list, and consigned to the scrap heap in July of last year. The hull was protected by the latest 12-inch armor plate, in sections arranged on the vessel at various angles.

An eyebar made by the American Vanadium Company was recently tested to destruction by the American Bridge Company. The test bars, which were of vanadium nickel steel, measured 14 inches by 2 inches by 35 feet. The results showed an elastic limit of 80,840 pounds, and a tensile strength of 99,890 pounds per square inch, with an elongation of 32.5 per cent in 12 inches, and a reduction in area at fracture of 52.3 per cent. Part of the bar was bent cold under a 14,000-ton press, and flattened upon itself without sign of fracture. Should the matter of price not prove an obstacle, this will be an ideal material for the eyebars of long-span bridges.

Efficiency tests are conducted by officials of the Pennsylvania Railroad, who, at unusual times and places, set signals of caution or danger, display fusees, or place torpedoes on the track, with a view to keeping all employees constantly on the alert for signals. During the tests for 1909, the following records were made by the men: Block signal rules, 47,384, of which 99.6 per cent showed perfect observance on the part of the employees, 45,887 tests of rules governing flag men, use of fusees, torpedoes, and other signals, 99.6 per cent perfect. Altogether, some 300,000 efficiency tests showed a practically perfect record for the employees.

Acting in accordance with the Spooner act of June 28th, 1902, which states that "the President shall cause to be constructed such safe and commodious harbors at the termini of the Panama Canal, and make such provisions for their defense, as may be necessary for the safety and protection of said canals and harbors," President Taft has asked for an appropriation of $4,000,000 for the commencement of suitable fortifications. He indorses the report of a special board of officers of the army and navy, which provides, we understand, for an adequate defense by batteries mounting the new 14-inch gun. The total cost of the completed fortifications will be about $15,000,000.

A most commendable movement in the anthracite region of northeastern Pennsylvania is the introduction of mine schools. In former days, the English-speaking and Teutonic races, skilled in mining, predominated in this district; but to-day work is done by a class of Europeans whose traditions and experiences have nothing to do with mines. Several of the mining companies have established schools for the benefit of these employees, one of the first of which was that established by the Philadelphia & Reading Coal and Iron Company. Here, in attendance, are found the apprentices and journeymen employed in the shops, and the mine workers. The course, which includes mathematics and drawing, has special reference to the particular class of work in which the attendants are engaged.

## ELECTRICITY.

In his presidential address before the American Electro-Chemical Society at Pittsburg, Dr. Leo H. Baekeland stated that "the last hundred years, under the influence of the modern engineer and scientist, have done more for the betterment of the race than all the art, all the civilizing efforts, all the so-called literature of past ages, for which some respectable people want us to have such an exaggerated reverence."

The thirty-third convention of the National Electric Light Association, which met at St. Louis last week, reported a very prosperous year, in which 2,200 members were added, bringing the total membership up to 5,270. The association began in 1885, with a membership of only 71. There are 820 operating companies represented in the association, and these constitute 90 per cent of the capitalization of the electric light industry in this country.

A new form of mercury-rod interrupter has been developed, with the object of producing a sharper break. It consists in covering the mercury with a quenching liquid. As the rod is withdrawn from the mercury, a bubble of vapor from the quenching liquid forms on the end of the rod and tends to press the mercury level suddenly downward at the break, thus effecting a more perfect current interruption, even though the rod may rise comparatively slowly from the mercury.

The New York Legislature has passed the bill which places telegraph and telephone companies of the State under the supervision of the Public Service Commission for the second district. The bill empowers the Commission to investigate and regulate the rates and service. The companies are required to file annual reports, and the Commission may veto any privileges under the franchises of the companies which have not as yet been exercised. Reduced rates, passes, or franks for the transmission of messages are prohibited.

A novel ventilating system has recently been developed, which consists of a small electric fan connected to the window sill in such manner that it may be operated either to draw in air from the outside or to exhaust the air from a room. It is suggested that the value of this will be appreciated in a kitchen on ironing day, or when any baking is being done, as it prevents the heat from spreading through the entire house, besides making the kitchen itself more comfortable to work in.

In order to determine the heat generated by concrete when hardening, six thermometers of special construction are to be imbedded in the concrete walls of the Gatun locks of the Panama Canal. Each thermometer consists of an iron cup in which is a resistance coil. This is connected by a pair of lead-sheathed copper wires to an indicating instrument and a small storage battery. Variations in the temperature of the coil produce variations in the electrical resistance, and this is indicated on the instrument, which is calibrated to show degrees of temperature. The instrument keeps a continuous record, which should prove of considerable scientific interest and importance.

It is a difficult matter to measure very high tensions of electrostatic or Wimshurst machines, owing to the glow discharge which is apt to occur above 40,000 volts. A new method has been adopted by Prof. C. F. Guye and Mr. A. Tscherniavski, which was recently submitted to the French Academy of Sciences. This consists in inclosing the spark gap and the electrometer in a substantial box, in which compressed gas is introduced. According to the Paschen law, the disruptive potential is approximately proportional to the gas pressure. Thus, with a given potential difference, the electrodes of the spark gap can be approached to each other in proportion to the increase of gas pressure, and by this shorter gap the electrostatic effects are reinforced, insuring more accurate readings. This method has been employed in measuring the tension of a Wimshurst machine, which showed a voltage of 80,000 with a pressure of from 4 to 9 atmospheres in the inclosing box.

Last November there was a series of heavy snow storms in Germany, which did considerable damage to overhead telephone and telegraph lines. As a result, a careful investigation was made of the question of putting such lines underground, and it was found that by using the Pupin system, underground cables could be used to good advantage on lines of less than 600 miles in length, with wires not more than three millimeters (0.118 inch) in diameter. The advantages of the underground system were found to be as follows: That there would be no interruptions due to external causes, that there would be no danger of cross talk, that the efficiency of the line would always be constant, that there would be no interruptions or expenses for repairs, due to external causes, and that while laying the cables extra wires could be provided, which would permit of further expansion to meet future demands. It was also shown that telegraph and telephone lines could be laid in the same cables without danger of inter-disturbance.

## SCIENCE.

Mr. Charles H. Peck, botanist of the State of New York, in his annual report states that the known species of edible mushrooms in New York amounts to 200. Five new kinds of edible mushrooms were discovered in the last year.

Dr. Charles Forbes, of the Department of Physics in Columbia University, has installed in Barnard College the first permanent apparatus for the installation of the Foucault experiment, to show the motion of the earth. Dr. Forbes set up a temporary apparatus for the experiment in St. Paul's Chapel of Columbia University some two years ago, which was described in these columns.

Dr. William Phipps Blake, a member of the first class ever graduated from the Sheffield Scientific School of Yale, died recently at Berkeley, California, shortly after he had received the degree of LL.D. from the University of California. Prof. Blake was 84 years old. When he graduated from Yale in 1853, he became the geologist and mineralogist for the United States Pacific Railroad expedition. His numerous activities included the editing of the Mining Magazine, geological work for the Japanese government, the exploration of a section of Alaska, the teaching of mineralogy and geology in the College of California, a geological examination of Santo Domingo, and the teaching of geology in the University of Arizona.

The satisfactory examination of the absorption spectra of glass of various sorts requires, in addition to the thermopile, a spectrometer with glass or quartz lenses and prisms, and the exact determination of the wave length of the limit of transparency requires the use of a slit with very sharp edges, a camera with an excellent lens, and a source of light the spectrum of which contains many sharply-defined lines and extends far into the ultra violet. The spectra hitherto employed for this purpose including the spark spectrum of an alloy of cadmium, zinc, and lead, the spectrum of mercury, obtained by means of the vacuum tube or the electric arc, the spectrum of the carbon arc and even that of the Heraeus amalgam lamp (mercury, lead, bismuth, zinc, and cadmium), contain too few lines to give satisfactory results. Zickendraht has recently employed the arc spectrum of iron, which, because of its extraordinarily large number of lines of accurately known wave length, appears especially well adapted for the study of absorption in glass. A Zeiss spectrometer with quartz lenses and prisms was used. The results, which are published in tabular form, are too complex to be briefly described.

Prof. Haber claims to have solved the problem of the direct synthesis of ammonia from its elements nitrogen and hydrogen. The process has been purchased by the well known German establishment, the Badische Anilin und Soda-Fabrik. If the process is as practical and economical as its inventor claims, its introduction will quickly cause a revolution in a comparatively new but already important branch of industry, the manufacture of artificial nitrates. In several countries possessed of abundant water power, large nitrate factories in which oxygen and nitrogen are combined directly by means of the electric arc, are in operation. Prof. Haber gives a few details concerning his process, but states that the combination of hydrogen and nitrogen is effected at a temperature of about 1,000 deg. F. and a pressure of 200 atmospheres. In a recent lecture he exhibited an experimental apparatus which produced three ounces of liquid ammonia per hour. The presence of a catalyzer is required to accelerate the combination. For this purpose, Prof. Haber employs uranium, but the rarity of this element appears incompatible with its employment on a commercial scale.

The adulteration of food in France is said to result in a profit of one hundred million dollars per year. Bread, which may be called the national food of France, has long been adulterated largely with talc, a substance which is not only indigestible, but is exceedingly irritating to the gastro-intestinal mucous membrane because of the sharp crystal fragments which it contains. Flour is often mixed with alum or with potassium carbonate to increase the amount of water absorbed, with zinc sulphate to keep the bread fresh, with copper sulphate and ammonium carbonate, to diminish the quantity of yeast required and to improve the appearance of bread made with spoiled flour. Denatured alcohol, costing one-eighth the price of pure alcohol, is used for the manufacture of the liqueurs and *apéritifs*, which are so largely consumed in France. Alcohol, denatured by the addition of methyl alcohol, is mixed with an equal volume of water and exposed for a few days to the sun, air and rain, which have the effect of precipitating the methyl alcohol so completely that its flavor remains barely perceptible. The mixture is then brought to the desired alcoholic strength by the addition of strong spirits, flavored to suit the taste of the consumer and sharpened by the addition of a pint of nitric acid to each barrel.

# A COMMERCIAL ROTARY ENGINE

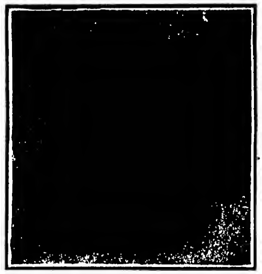
## PRACTICAL SOLUTION OF AN AGE-LONG PROBLEM

Elsewhere in this issue we have discussed editorially the problem of the rotary engine and set down the mechanical difficulties which must be mastered before a successful engine of this type can be produced. Reference was made to the fact that a recent rotary engine has undergone a successful laboratory test at the Stevens Institute and a successful commercial test of six months' duration at the plant of a leading contractor in this city This engine, which was designed and built by Mr Gerardus P Herrick, of 74 Broadway, this city, forms the subject of the accompanying illustrations. The principal distinguishing features—those which contribute more than any others to its success—are, first, the fact that reciprocating movements are entirely eliminated, all of the movements being rotary and secondly, that the main shaft of the engine runs upon a film of steam, whereby the destructive thrust, transverse to the axis, is completely counterbalanced

MECHANICAL FEATURES.—The engine consists of two rotors or drums of equal diameter, placed one above the other, and running with the barest clearance between their peripheries By means of external gears, they are caused to rotate in opposite directions at the same speed Tho upper drum rotates within a closed cylindrical casing, between the walls of which and itself there is a bare micrometer clearance The lower, or what we might call the power drum, rotates within a casing of larger diameter than itself, and it is provided with a rectangular piston which fills the annular space between the external periphery of the drum and the internal periphery of the casing This drum and its attached piston also rotate within their casing with only a micrometer clearance between the adjacent surfaces. The peripheries of the upper and lower casings intersect each other sufficiently to allow the upper drum to project within the lower casing until it rotates with only the slightest clearance between itself and the power drum

VALVE MECHANISM.—Sunk in the upper drum is a transverse, semicircular recess, which serves at once as a pocket to admit the piston of the lower drum as the two drums roll together, and also as an admission valve for the live steam, the proper registering of the piston with this pocket being assured by the fact that the two drums are geared together Steam is admitted on one side of the engine and exhausted on the other The successive admission expansion, and exhaustion of the steam are simple and easy to understand As the piston (which, viewed from the side of the engine shown in our drawing, moves opposite to the hands of the clock) clears the pocket in the upper drum the latter moves forward until its leading edge clears the lower edge of the steam inlet, when live steam is admitted to the annular space back of the piston and continues to flow therein until the after edge of the pocket has swung round clear of the steam cylinder This point of cut-off is the position chosen for the accompanying illustration. During the rest of the stroke, the steam works expansively, until the after face of the piston clears the forward edge of the exhaust ports, which are shown in dotted lines at the end of the circular path swept through by the piston

STEAM COUNTERBALANCE.—The most original and valuable feature of this engine is the ingenious method by which the heavy load on the main shaft, due to the radial steam pressure in the cylinder, is exactly counterbalanced by a steam pressure acting in the opposite direction, the roter being balanced in its own steam This is accomplished by means of what are known as balancing plugs, which are inserted in steam balancing chambers. There are two of these plugs, one on each side of the engine. They are made of sufficient length and diameter to provide an area which, at any part of the stroke, is exactly equal to the area of the surface of the drum which is under the pressure of the live steam For a little over half their periphery, and on the side immediately opposed to that portion of the annular cylinder space upon which the heaviest steam pressure is developed, the balance plugs are provided with a series of recessed steam pockets, and steam is admitted to these pockets successively by a series of holes drilled through the drum. Consequently, the thrust of the steam toward the shaft of the rotor is, for all positions, constantly balanced by an equal thrust of the steam away from the shaft. Perfect balance is secured, the rotor practically running upon a fine film of live steam. The advantages of this ingenious arrangement are that not only are [illegible] friction and destructive, uneven wear at the main journals prevented, but it is possible to mount the rotor on finely adjusted ball-bearings, whose duty is simply to keep the rotor in true axial alignment.



The piston is shown at cut-off. Note small holes back of piston to admit steam to balancing-chambers.

**Rotary engine with side plates removed**

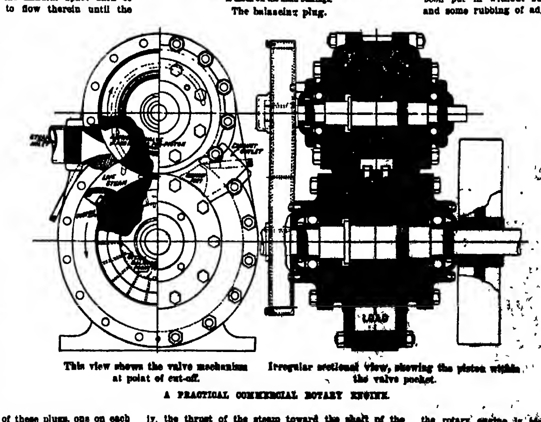
By this device the rotor rides on a film of steam and the load is taken off the main bearings.

**The balancing plug.**

ABSENCE OF RUBBING SURFACES.—Another feature which has contributed largely to making this rotary engine practical, is the abolition of packing devices between the adjacent moving surfaces. Knowing the impossibility of keeping the usual packing devices steam-tight, Mr. Herrick decided to abolish them, and reduce leakage by machining the parts so carefully that they could be adjusted to run with the smallest micrometer clearances. That this has been accomplished successfully is proved by the fact that in the tests at Stevens Institute, this engine developed [illegible] brake horse-power on a steam consumption of [illegible] pounds per brake horse-power per hour; which compares favorably with the steam consumption of the average reciprocating engine of similar capacity. It will be realized that by getting rid of packing devices and introducing a system of steam balancing, Mr. Herrick has not only prolonged the life of the rotary engine, but he has greatly increased its output by getting rid of that accumulated friction which, in earlier forms of the rotary, was sufficient to cut down the economy to a point which rendered them commercially unserviceable

LABORATORY TESTS.—In his report of the laboratory tests at Stevens Institute, Prof Pryor states that he obtained the following results With a steam pressure of 145 pounds and 1,006 revolutions per minute, 20 48 brake horse-power was obtained with saturated steam, on a consumption of 50 7 pounds of water per brake horse-power per hour With a steam pressure of 185 5 pounds and 55 deg. of superheat, the engine at 1,008 revolutions per minute developed 20 40 brake horse-power on a consumption of 44 4 pounds of water per hour In commenting upon these tests, Prof Pryor says of the engine "Its steadiness of operation, its lack of vibration, and its output per cubic foot of space occupied, should be particularly commended"

COMMERCIAL TEST.—To test its commercial value over a long period of time, the engine was coupled to a dynamo at the Degnon Contracting Company's plant in this city, and from August 14th to December 21st, 1909, it served to produce the current for lighting the plant day and night. It was run for 1,685 hours, or the equivalent of more than six full working months. At the end of this time, it was again tested at the Stevens Institute; when, under similar conditions of revolution and steam pressure to those which obtained at the first test, the steam consumption was found to be 52 6 pounds, the slight increase being attributed by Prof Pryor to the fact that new ball bearings had been put in without sufficiently careful adjustment, and some rubbing of adjacent surfaces had occurred



This view shows the valve mechanism at point of cut-off. Irregular sectional view, showing the piston within the valve pocket.

A PRACTICAL COMMERCIAL ROTARY ENGINE.

FUTURE FIELD OF THE ROTARY.—Apart from the field of usefulness open for the rotary because of its compactness, simplicity, perfect balance, and moderate steam consumption, there is a far wider and more important field presented in connection with the steam turbine. We have frequently in this journal drawn attention to the fact that the steam turbine is most efficient in the lower ranges of the expansion of the steam; and that in the higher ranges, because of leakage over the ends of the blades, it is not so economical; and that at low speeds it is decidedly uneconomical. Furthermore, the turbine cannot economically make use of high-pressure steam or of superheated steam, and consequently it is shut out from all those well-known economies which the use of high-pressure and large superheat secure. Now the rotary engine is ideally adapted for both high pressure and superheat, and this fact is recognized by L. D Lovekin, the chief engineer of the New York Shipbuilding Company, [illegible] "A practical rotary [illegible] with any [illegible]

# THE COSTLIEST EAR OF CORN IN THE WORLD

BY FRANK C. PERKINS

THE COSTLIEST EAR OF CORN IN THE WORLD

In the accompanying illustration we present ten champion ears of corn, which were sold at the rate of $1,345 per bushel, or $335 for the ten ears, one of the highest prices, if not the highest price, paid for that number of ears of corn. The champion single ear of corn was sold at the Omaha National Corn Show for $85, or at the rate of $5,950 per bushel, which is said to be the highest price ever paid for a single ear of corn. The champion ten ears of corn shown in the illustration average 10½ inches in length and 7⅝ in circumference, each ear carrying 20 rows of kernels, the depth of the kernels being ⅝ of an inch, and the average weight of each ear was 20 ounces. Prize agricultural products such as these may not be adapted to all localities, for which reason one must not be misled by the awarding of a prize. In some localities the prize corn might not be so profitable, or at least not so profitable as other varieties. Furthermore, the price at which ears of corn are sold may be a fictitious or a forced one. A farmer may take a prize at a fair. When the corn is put up at auction, the farmer, having received a large amount as premium for the champion corn, can afford to bid it in at a higher price than his competitors. The high price paid would therefore be for advertising purposes. Lastly it must be considered that from a large field of corn some large specimens may be selected. This does not prove that the selected specimens are the best, but merely the largest.

# A GIANT RUHMKORFF COIL

BY JACQUES BOYER

The first induction coil was made by Masson and Bréguet in 1842, but it was not until 1851 that Ruhmkorff gave the instrument its definite form, which has not sensibly varied since that time, although it has been improved and modified for various applications. Ruhmkorff increased the number of turns of wire of the secondary circuit, for which he employed a very fine and very long wire. Perfect insulation was obtained by saturating the coil with gum lac and the intensity of the magnetic force was increased by inserting a core of parallel iron wires inside the concentric coils. These wires are magnetized by the primary current and the magnetic flux produces currents in the secondary circuit.

The principal improvements which have been made in Ruhmkorff's original coil are the following. In the first place, Fizeau increased the power of the instrument by connecting the ends of the primary coil with the electrodes of a condenser, composed of sheets of tin-foil, insulated by silk and placed in the base of the instrument. The extra current which is formed on breaking the primary circuit flows into this condenser instead of forming a spark. The primary current is thus arrested more suddenly and the electromotive force of the induced current is correspondingly increased. For the construction of large induction coils [illegible] the method of dividing the [illegible] the other. This method avoids the production, between two adjacent turns of wire, of a difference of potential sufficiently great to pierce the intervening insulation.

The interrupter, by which the primary circuit is broken at very short intervals, was improved by Ducretet, by giving it the form of a vibrating strip of metal, fixed at both ends and bearing at its middle point a plate of soft iron. The primary current flows through this plate and a metal point in contact with it. This contact is broken by the attraction which the core of the instrument, when magnetized by the passage of the primary current, exerts upon the iron plate. But this attraction ceases as soon as the circuit is broken, and contact is then immediately re-established by the elasticity of the vibrating strip of metal. In this way a rapid interruption is produced. Very large induction coils are usually provided with Foucault's mercury interrupter, operated by a separate battery of one or two cells.

One of the largest induction coils ever made was constructed long ago in England for Spottiswoode, by the instrument maker Apps. Its length was 48 inches, its external diameter, 19½ inches, its total weight, 1,675 pounds, and the weight of its core of soft iron, 67 pounds. The primary circuit consisted of 3,150 feet of wire of a diameter of 1/10 inch. The length of the secondary circuit was 280 miles. It consisted of 341850 turns of wire. This apparatus, operated by 30 Grove cells, produced a spark 40 inches long.

A GIANT RUHMKORFF COIL.

A still larger coil was recently constructed in Paris by Carpentier. The secondary circuit of this instrument is composed of 97½ miles of copper wire of a diameter of 1/125 inch. The soft iron core has a length of 80 inches and a sectional area of 9.3 square inches. The primary coil contains 792 turns of copper ribbon, about ¼ inch broad and 1/25 inch thick, arranged in six layers. The coil is surrounded by an ebonite tube more than ½ inch thick. This giant induction coil, operated by a current of 110 volts and 30 amperes, produces a spark about 50 inches in length.

The Canadian Government have appropriated $50,000 for experiments in electrical smelting, which are to be conducted under the supervision of Dr. Eugene Haanel, superintendent of mines for the Government of Ottawa.

## FIRE FIGHTING WITHOUT FIRE ENGINES.

BY HERBERT T. WADE.

The practical elimination of the fire engine from fire fighting in the business section of lower Manhattan has been brought about by the successful use of the high pressure independent fire service. Good results have attended also this modern method in Brooklyn, Coney Island and Philadelphia, and in all of these places independent systems of high-pressure mains supplied from central pumping stations now are essential and established elements in much needed fire protection. The frontispiece of this week's SCIENTIFIC AMERICAN illustrates the method and its application by the firemen, and while it is not intended to represent any particular plant, yet it shows the essential features of a modern high pressure pumping station with motor-driven pumps and the use of the hydrants along the distribution system, such as are employed in New York city.

Now if a pressure of water at the hydrant can be maintained as great as that furnished by the pumps of a fire engine, then the latter of course is superfluous, and that, along with adequate water supply, is what, in short, the high pressure system accomplishes. This condition, however, so successfully realized, has been made possible only by modern mechanical and electrical engineering, to which the firemen have added by intelligently studying and applying the new resources at their command. Referring to our illustration, it will be seen that the pumping station has two sets of intakes for its water supply—one for fresh water and the other, which is in connection with a vacuum pump, for salt water. In the case of the New York system, the Croton water is used under all normal conditions, and the mains are kept filled at the ordinary city pressure. The drafts on the city's supply for fire purposes compared with the usual daily consumption are inconsequential, but the river or salt water may be drawn at any time through intakes extending direct to the pier slips, and is available in case of any failure in the fresh water supply or at a time of a large conflagration. For high pressure stations either gas or electric motors are available to drive the pumps, as there is always a supply of this kind of power from public service corporations distributed underground, and carefully protected and duplicated in such a way as to make any possible failure highly improbable. Thus in the Manhattan pumping stations the high-efficiency centrifugal pumps are driven by induction motors using alternating current from the Edison Electric Company, with direct connection with its Waterside station and duplicate connection with its sub-stations, provision even being made to connect with Brooklyn in case of emergency. A contract between the city and the company requires a constant reservation of power, and the simple operation of switches puts the machinery into full operation. The centrifugal pump has been found most advantageous, particularly with electric motors.

A high pressure system protects a given district where the mains and hydrants have been installed, and in the case of New York this territory extends from Chambers to Twenty-third streets, and lies between the Hudson River and the Bowery and Third Avenue. The pumping stations are located outside of districts likely to be affected by any possible conflagration, and free from danger from neighboring buildings. They are situated at South and Oliver streets and at Gansevoort and West streets. The hydrants in this system are of the type shown in the illustration, and are spaced along the mains at an average interval of 270 feet, and to reach a building on fire in no case would there be required a length of hose greater than 450 feet, an important consideration, as the pressure in a line of hose diminishes rapidly.

Let us assume that a fire breaks out in this protected territory, and the alarm is transmitted in the usual way, either from a street box or an automatic fire-alarm telegraph to fire headquarters. Thence it is sent out over the fire-alarm circuit to the various fire houses in the city, including the two high-pressure stations. At these stations night and day there is always an operator on duty who sits at a telephone switchboard by which the station can be put in communication not only with the scene of fire but with headquarters and with the other station. Special telephones in metal boxes are distributed in close proximity to the hydrants through the high-pressure district, and connect direct to the station, a special service being maintained by the telephone company. In front of the operator is a large board containing the numbers and locations of the various alarm boxes throughout the district, those to which his own station responds immediately being designated in red. The alarm comes in over the regular circuit, the gong sounds the appropriate number, which is also registered by perforation on a tape, on which also is printed the time by a clock. If the alarm is one for the station, the operator immediately grasps the lever of the marine telegraph, and the signals to start are sounded and shown on the large indicator on the wall. The crew spring immediately to their places, the chief engineer at the switchboard and the oilers and machinists at their appointed stations. From the switchboard everything can be controlled and regulated. The current is switched to the motors, and the ponderous pumps are soon revolving, another switch opens electrically-controlled valves regulating the water supply, while recording and other meters and indicators are before the eyes of the chief engineer. Not every fire requires the flood of water that can be set in motion from the station, and the standing order is to start one pump, regulating the pressure at the outlet at 125 pounds. The next order must come from the chief of the fire department at the fire, and may be a call over the telephone to increase both water supply and pressure or an order to shut down the pumps. As shown in the picture, the chief at the fire is even in closer touch with the pumping station than he could be with a number of separate engines located at the scene of activity. The scene within the station when the pumps are in operation is hardly one of extraordinary activity, and no greater excitement is manifested than in a well-appointed power plant. The electric control of the chief is so complete that he does not need to leave his position at the switchboard, and with ear open for orders and eye on his meters and indicators, the entire situation is at his command.

Outside with the firemen there is naturally more activity, and high pressure working has occasioned certain changes in equipment and methods. From the beginning the high pressure required the best and strongest hose procurable, and this in sufficient quantity is carried in large wagons. These hose carts are moved from the rear of the fire houses, from which they followed the engines, to the front and are given right of way over other apparatus in the streets. When the reliability of the high-pressure service was established, for most alarms the engines were not sent out, but held in reserve in the fire houses. In two houses the engines were entirely removed and double section hose companies maintained. As the hose is heavy, the work of carrying and hauling it is particularly arduous, so that, in this respect, the labor of the firemen at the fire has not been lightened by mechanical progress. The automobile hose wagon used by the New York Fire Department, however, has demonstrated its complete usefulness for transporting the heavy loads of 3 inch hose much more rapidly than the tenders drawn by horses. Immediately on reaching the fire, the hose is unloaded, a length connected with the hydrant outlet, of which there are four, and successive lengths are laid to the scene of action. The former engineer of the fire engine with his lever key takes his position at the hydrant and watching the pressure gage at the outlet, opens or shuts the valves as ordered. The line is stretched where the exigencies of the occasion demand, perhaps to the standpipe connection, which must be placed at the sidewalk close to the building walls, and which connects with the standpipe itself within the building with its outlets and hose reels on each floor. It is this that affords the fire protection to a skyscraper, in addition to the pumping plant of the building, and must be used by the firemen for the higher stories, or it may be used to deliver a stream to a fire in an adjoining building. The connection may be made to the sprinkler system of the building through a similar outlet or to a cellar pipe to flood the basement, or, as shown in the illustration, two lines may be siamesed into the water tower. The permanent nozzle holders of the hose wagons may be used, while for a single stream the tripod nozzle holders are employed, as the powerful pressures render holding the hose and directing it practically impossible even for two or three firemen. The hose may even have to be hoisted up onto a fire escape, and there fastened or clamped with one of the devices which have been developed for this purpose. Now a single line from one of the four outlets is practically as powerful as that derived from a fire engine, so that the concentration of pumping power on any single block can be appreciated. Further, when it is realized that these streams can be delivered with a force sufficient to tear off cornices and make their way into the very seat of the fire, their power may be appreciated.

The New York Fire Department's use of the high-pressure system has been most successful, and quite on a par with the excellent engineering involved in its design and construction. A sufficient quantity of water is brought to bear at the earliest possible moment, and this usually quenches any ordinary fire in short order. If, however, it proves stubborn, then it is straightaway drowned out in the building where it originates, and in no case since the high-pressure service has been used in New York, has a fire progressed beyond the building where it began. In the extension of the system on the East Side of the city the distribution mains will be laid duplex in adjoining streets, passing out from the pumping station into two systems of mains, ordinarily connected but capable of being isolated by the gate valves at the station and by distant electrically-operated valves at some point of intersection. With the Philadelphia system, which incidentally uses gas motors and direct-acting pumps, in use for a number of years, and which has recently been extended, and with a well-planned project under way in San Francisco, it would seem that the day of the fire engine had passed and that the central fire protection method would soon take its place in many other large cities.

---

### A High-Pressure Fire Reduction Valve.

Soon after the successful inauguration of the high-pressure fire service in New York city, the SCIENTIFIC AMERICAN* called attention to the need of a suitable regulating valve to be used at the hydrant, in order to render possible the control of the pressure on any single line of hose and its adaptation to the work in hand. The need of such a valve has become increasingly apparent.

For some purposes, as for a water-tower or the stand-pipe of a skyscraper, the highest pressures may be demanded, while for other lines at the same fire low pressure streams which the firemen can hold and manipulate readily are required, as for the lower floors of the same or an adjoining building. What was needed, as was pointed out in the SCIENTIFIC AMERICAN, was a device light and portable, that could be applied readily with the hose at the hydrant outlet and enable any pressures from zero to the maximum at the hydrant to be passed with a minimum loss in volume of water from friction and otherwise.

This seems to have been secured in the Kiely and Mueller valve, which recently has undergone some thorough tests by the New York Fire Department, and has been adopted for high-pressure companies and fire-boats.

The valve is small and compact, designed to be transported on the hose tender with the smaller tools. There are two pressure gages, one on the inlet side showing the pressure at the hydrant furnished by the pumps, the other the reduced pressure as the water passes out of the valve into the line. After the hose has been stretched, the engineer opens the central valve of the hydrant with his key wrench, and then the gate valve to the outlet from which the line is taken. The handle of the regulating valve is screwed down, allowing no water to pass. A half turn of the handle in the direction of an indicating arrow allows water at a pressure approximately of 15 pounds to pass, a full turn 30 pounds, and so on up to the full or hydrant pressure. In short, the pressure on any line from such a valve is entirely under control, and the engineer merely has to watch his gage and turn his handle until the desired point is reached, when the pressure is maintained automatically.

In a recent test before the engineers of the New York Department of Water Supply, Gas, and Electricity witnessed by the author as the representative of the SCIENTIFIC AMERICAN at the St. Edwards High Pressure Station in Brooklyn, it met every condition imposed. Different pressures from 75 to 300 pounds were put on the mains by the pumps in the adjacent station, and the pressure on the line was reduced as ordered by simply turning the handle of the valve. Thus when over 240 pounds was recorded at the hydrant, 40 pounds was delivered at the nozzle. The adjustment and maintenance of any desired pressure were far more easily and satisfactorily controlled than would be possible with a steam fire engine. Variations in the pressure on the mains did not affect sensibly the operation of the valve, while when the line was shut down at the nozzle no effect was manifest.

The valve consists essentially of a valve body, containing a seat, main disk, piston, auxiliary valve; a diaphragm, a compression spring, an adjusting screw, a handle, and a small hand-operated by-pass valve. The disk and piston are constructed of one piece, and the portion of the metal connecting the disk and piston has in it a small port through which high pressure passes up over the piston, which, being of greater diameter than the disk, drives the latter down to its seat, thus shutting off the pressure. The next part of the operation is brought by the opening of the auxiliary valve mentioned above, which being of greater diameter than the port through which the high pressure is conveyed to the top of the piston, quickly causes a reduction of pressure on the piston side sufficient to allow the initial pressure to open the main valve or disk. As soon as the reduced pressure has become sufficient to force the diaphragm up against the pressure exerted by the adjusting spring, it causes the auxiliary valve to close, thereby bottling up the pressure above the piston, which, owing to its greater area, causes the main valve to close. This operation is repeated as often as occasion may require. The function of the small by-pass valve also mentioned is to enable it to cause full pressure to flow through the valve when desired, as in a sudden emergency. The power to operate the valve is furnished by the initial pressure, whereas in most reducing valves it is the reduced pressure acting on the diaphragm [illegible]

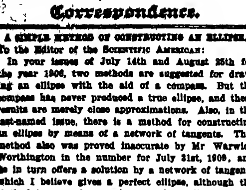
### A SIMPLE METHOD OF CONSTRUCTING AN ELLIPSE.

To the Editor of the SCIENTIFIC AMERICAN:

In your issues of July 14th and August 25th for the year 1906, two methods are suggested for drawing an ellipse with the aid of a compass. But the compass has never produced a true ellipse, and these results are merely close approximations. Also, in the last-named issue, there is a method for constructing an ellipse by means of a network of tangents. This method also was proved inaccurate by Mr Warwick Worthington in the number for July 31st, 1909, and he in turn offers a solution by a network of tangents which I believe gives a perfect ellipse, although the method is somewhat cumbersome for ordinary use

There is, however, a simple way of constructing an ellipse of any desired dimensions solely with the aid



A SIMPLE METHOD OF CONSTRUCTING AN ELLIPSE

of straight-edge and pencil. No originality belongs to my method, but it is readily proved to accord with correct mathematical principles

On a straight-edge or ruler mark off a distance *QP*, equal to half the desired major axis, also, from point *P*, a distance *PM*, equal to half the desired minor axis

Referring now to the drawing, we construct perpendiculars *AA'* and *BB'*, and lay the ruler down so that the points *Q* and *M* fall exactly upon these perpendiculars. The point *P* will then fall somewhere on the curve of the proposed ellipse By shifting the ruler about, in such a way that *Q* and *M* always fall on lines *AA'* and *BB'*, respectively, the mark on the ruler at *P* will give the position of any number of points, which afterward may readily be joined by a continuous line EDWARD M WEYER.

Washington and Jefferson College, Washington, Pa.

### Astronomical Photography.

BY F V COLLINS.

The plan of photographing the entire heavens originated with Monches in 1887 The death of this eminent man of science was one of the adverse factors which have conspired to delay the work, which now, however, promises to draw to a triumphant conclusion

The importance of the universal photographic star chart to the astronomer of the future cannot be overestimated It is now generally acknowledged that the stars are in motion with respect to one another, and our entire solar system is in motion through space, so that one day the constellations will be seen from a sensibly different point of view Changes will come to pass in the apparent arrangement of the star groups, and in the course of years they will develop, so that something may ultimately be discovered of the real structure and laws of the distant bodies of the universe It may be that the chart now being prepared will enable the astronomer of some centuries hence to learn as much of the great universe of stars as we know of our comparatively minute solar system revolving within it.

Though photography has been demonstrated of late years to be the only method of revealing the structure of those fascinating formations, the nebulæ, at all adequately, the star chart on a large scale, though it be more prosaic to lay observation, possesses an incalculable value of itself The wonderfully accurate photographic chart may lead, with the aid of a correspondingly accurate system of measurement, to the discovery of entirely new laws of the universe which directly affect our own planet. Seth Chandler discovered the law and evaluated the magnitude of an oscillation in the position of the axis of the earth's figure, which had for years puzzled his astronomical colleagues, not as a result of any special series of observations made for the purpose, but upon the examination of measures made for divers ends at numerous observatories throughout the whole of the last century. And so it has always been a result of measurement when any great advance has been made in a knowledge of the laws which govern the universe. So it will have to be in the solution of the problems which confront astronomers to-day in every direction. The photographic chart, by making these measures more rapid and more certain than is possible by the old visual method, has practically revolutionized this most valuable field of astronomical research.

[illegible] of the superiority of the photographic chart over the older method of observation is quite simply explained. The image of a star in the telescope is very rarely absolutely steady, for the light, prior to its reaching the instrument, has to pass through the veritable sea of our own atmosphere, constantly disturbed, in practically all portions, by cold and hot-air currents Rifle shots are familiar with the sort of effect which is thus produced. On a blazing hot day, when currents of air are rising from the heated ground, the target seems to dance before the eyes, growing taller and shorter and breaking in pieces, with the bull's eye now in one corner and now altogether vanished Something of the same thing happens to the star image when the telescope is set up in any but a very few tranquil places, and especially when it is in a country much broken up by mountain chains or arms of the sea On all but two or three nights in the year the star image will be seen dancing and quivering in the telescope, more or less as the air is much disturbed or uniform And when the observer tries to set the spider line of his measuring apparatus upon the image, he has to make some sort of estimate of its mean position and set upon that. It is really surprising how accurately this can be done after long experience, but the unsteadiness of the object is bound to set a limit to the accuracy which even the most practised observer can obtain Now it might be thought that this constant vibration of the object would be more fatal to the photograph than to visual observation, but this is not the case For the motion is very rapid, several times a second does the star make a small jump from its mean position and return to it, and, on an average, it jumps every way with equal frequency The consequence is that the photographic plate, which keeps a record of every jump, produces in the end an image which is certainly larger than it ought to be, but which is, as a rule, enlarged equally in every direction, so that its center remains still where the center of the image belongs And when the plate is put under the microscope of the measuring machine—a device capable of accurately determining a fifty thousandth of an inch—and the threads which are moved by the measuring screw set upon the photographed image, the enlargement of the latter is more than compensated for by any advantage which accrues from a steady image

But the superiority of the astronomical photograph over visual observation is not confined to the star chart Numerous articles in popular periodicals have acquainted the general reader with the wonders of the nebulæ as revealed by the photographic plate The cumulative effect of light upon the latter renders it possible to obtain exquisite delineations of faintly luminous objects by means of a sufficiently long exposure. Vast new regions of space are thus being explored, and still vaster regions await further exploration Prof E Ray Lankester, in an address before the British Association, stated that "the invention of the dry plate, which has made it possible to apply photography to astronomical work is the chief cause of the great expansion of astronomy since 1881 ' To quote Prof Lankester further "It was the dry plate which made long exposure possible, and thus enabled astronomers to obtain regular records of faintly luminous objects, such as nebulæ and star spectra Roughly speaking, those visible to the naked eye may be stated as 6,000, this is raised by the use of the best telescopes to 100,000,000 But the number which can be photographed is indefinite, and depends on length of exposure, 1 000,000,000 000 can certainly be so recorded By the photographic method hundreds of new variable stars and other interesting objects have been discovered. New planets have been detected by the hundred Up to 1881, 220 were known During 1881 only one was found, namely, Stephania, being No 220, discovered on May 19th Now a score, at least, are discovered every year".

The appearance of Halley's comet this year suggests the fact that some of the most extraordinary revelations of photography in astronomy have been in the case of these strange members of the solar system The vast size and tenuity of comets render them very liable to disturbances from other celestial bodies The photographic plate has shown that the comets utterly transform themselves in a few hours' time These transformations are sometimes evidently due to gravitation from some neighbor, and again, apparently, from actual collision with planetary bodies or matter, which not only distorts but sometimes breaks the tail This was the case with one of the comets of 1893, where photographs on successive nights show the tail dissipated and broken, evidently by such an encounter. The presence of a new planet or of inter-planetary substance may be thus revealed. It is interesting to note that the present appearance of the comet of Halley will signalize the first occasion on which this famous body has been photographed.

According to Prof G. W Ritchey, of the Yerkes Observatory, it is now possible, with the aid of improved optics and mechanics, to construct a photographic reflecting telescope with as much precision and refinement as have been expended upon the great refracting telescopes. Prof. Ritchey has obtained splendid results from his two-foot photographic reflector, and his photographs thus obtained of the nebulæ have a wider appeal than to the scientific mind alone To many a person untrained in astronomical lore, indeed, the photograph of the great spiral nebula in the constellation of Andromeda, obtained with the Yerkes two-foot reflector, would probably appeal at once as that of a most marvelous spectacle—a vast planetary system in the making About the same proportion of the sun to the planets in our own system is to be observed in the great central spherical condensation of the whirling mass and the smaller condensations in the latter Some of these smaller condensations, at varying distances from the central semi-formed orb, have assumed an almost perfectly spherical shape, others, again, are formless, though vastly denser than the nebulous matter extending, in a circular or elliptical form, through out the entire spiral system It may be observed that the spiral character of this nebula was never even suspected until it was photographed in 1888 by Roberts with a reflecting telescope Yet the result then obtained was crude indeed when compared with what was obtained by the instrument at the Yerkes Observatory Seen by the naked eye, this great nebula appears only as an indistinct hazy spot among the stars. The greatest visual telescope in existence fails utterly to reveal the amazing spiral structure so brilliantly shown in the photograph

Judging from the results obtained with the two-foot instrument Prof Ritchey estimates that an eight foot reflector, if used in a climate where there are suitable atmospheric conditions, would photograph stars which are fifty times fainter than the faintest stars which can be seen with the largest modern refractors "This means,' says Prof Ritchey "that such a reflector would enable us to penetrate seven times farther into space than can now be done with the greatest visual telescopes, and therefore that such an instrument would reveal to us a universe seven times seven times seven—more than three hundred—times greater than the universe which is revealed by the most powerful modern refractors I know of no opportunity which has ever been presented to the entire history of astronomy greater than that which now awaits us in the construction of a large modern reflector and its use in astronomical photography "

It is estimated that the cost of such an instrument as Prof Ritchey advocates—that is, one of eight-foot aperture, and embodying the latest developments in optics and mechanics—would be about one-thirtieth that of building a battleship of the ' Dreadnought" type

### The Current Supplement.

One of the most important articles in the current SUPPLEMENT, No 1796, is that by George Neumann, in which the compulsory working of German patents is discussed, a matter of great importance to American manufacturers The adhesion of locomotives is a most important factor in designing engines, and must be considered at every step in the preparation of a general design An article on this subject appears in the current SUPPLEMENT Rose's excellent description of a profile puppet show, and how it can be made and used, is continued When shipbuilders commenced turning out iron and steel vessels, navigators found themselves confronted with the problem of overcoming the magnetic forces of their ships and making their compass needles point toward the magnetic north How the problem is solved is told by William C Ward in a paper entitled 'Compass Deviations ' Frank C Perkins writes on Canadian pulp making in the Algoma district, Ontario Irish linens and some features of their production are discussed by Sir William Crawford

Three kinds of bench marks were used by the United States Geological Survey in the spirit leveling in Ohio from 1898 to 1908, inclusive, according to a bulletin by Messrs S. S Gannett and D H Baldwin The first form was generally used in the vertical walls of public buildings, bridge abutments or other substantial masonry structures, being a circular bronze or aluminium tablet, 3½ inches in diameter and ¼ inch thick, appropriately lettered, and having a 3 inch stem cemented into a drilled hole The second form was employed where masonry or rock formation was not accessible, and consisted of a hollow wrought iron post, 4 feet long and 3½ inches in outer diameter, split at the bottom and expanded to 10 inches so as to resist pulling from the ground These posts were sunk 3 feet in the ground—after having been coated with asphalt—and a bronze tablet similar to the one already described was then riveted to the top. The third form was little used and is now altogether discontinued, being the ordinary split bolt of copper, 1 inch in diameter and 4 inches long

# HOW TO ESCAPE FROM A SUNKEN SUBMARINE

## METHODS APPROVED AND DISAPPROVED

In a diving manual recently published by Siebe, Gorman & Company, Limited, submarine engineers of London, we find some excellent suggestions on the subject of saving the crews of submarine boats.

The problem of saving the lives of a crew of a submarine vessel is by no means easy of solution. The equipment and apparatus which is invaluable on shore is quite useless under water. It would be quite easy to construct a submarine boat, the crew of which would be safe under practically every conceivable set of circumstances, but such a vessel would be so hampered by her safety devices as to have little or no military efficiency. In the opinion of Messrs. Siebe & Gorman it is essential that the salvage of the vessel and of the crew must be looked upon as entirely separate. Inevitable delays in the arrival of the salvage vessel and in getting purchase on, conditions of tide, weather, etc., render it almost certain that a submarine cannot be raised in time to save life.

It is taken for granted that an accident which will endanger the lives of the crew will result in the inrush of water in large quantities. A minor accident to the machinery would result only in an involuntary rush to the surface, owing to the reserve buoyancy of the boat, and any ordinary small leakage can be readily dealt with by the machinery at command.

When, however, there is a collision, or when, by some other mischance, a hole is made in the hull, the water enters freely, and the effect will be the descent of the vessel to the bottom. This may not be very fast, but, assuming that the water is entering more rapidly than it can be expelled the vessel will undoubtedly sink and continue to fill until she is either full, or, if not holed in the top, until the air in her is compressed to a pressure equal to that of the water at the depth in which she has foundered. As soon as the salt water comes into contact with the battery or with the terminals of the dynamo, if this be still working, chlorine is evolved, and the air remaining inside is vitiated.

If anything is done, it must be done quickly. Accordingly, the following steps must be taken:

(a) To render the crew independent of poisonous gases,

(b) To preserve the crew from drowning in the boat, and

(c) To provide means of escape from the boat, and ascent to the surface.

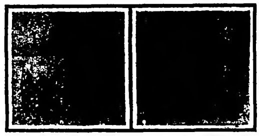
The devices to bring these about at present known are:

(1) Air locks for escape.

(2) Detachable chambers or life boats.

(3) Self-contained dress for escape.

Air locks alone are of little use except in shallow water, but combined with (2) or (3) are essential in all methods of escape. The air lock may be a portion of the boat provided for the special purpose, or the general cavity of the boat may be used, in which case the pressure inside the vessel can be made equal to that of the water outside by simply allowing the water to enter, for it is manifestly impossible to open an aperture until the pressures at both sides of it are equal. The great objection to all forms of detachable chambers or life boats is their size, weight, and resistance, if made large enough to contain all the crew of a modern submarine, and as such a chamber would have to be carried as a superstructure, it would be in the likeliest position to be injured in case of collision. Moreover, what is further against any device of this kind is that the crew are expected in a moment of considerable excitement to undertake an entirely novel operation which there is no means of trying previously. Experience has shown that even plain drop safety weights fail at the critical moment.



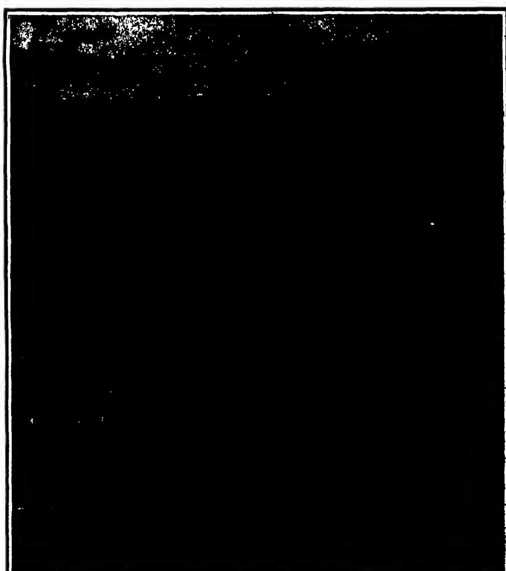
The diagram on the left shows a longitudinal section of a submarine, showing an air trap in use, three men under the trap in safety helmets, and one emerging from the conning-tower; that on the right a transverse section of a submarine, showing air-traps in use, men seated in the air traps, wearing safety-helmets, and a man emerging from the conning-tower.

VARIOUS METHODS OF ESCAPE.

A life-saving device to be efficient must be able to fulfill promptly the three conditions, a, b, and c, previously referred to, and in order to meet them a special form of diving helmet has been designed by Messrs. Siebe & Gorman which is quite self-contained and not dependent on any feature which is liable to get out of order. The helmet, which is large enough to allow the head free movement, is sloped away to fit the shoulders, and is connected to a short jacket of strong waterproof material. In front of the jacket, inside, is a pocket containing a combined air purifier and oxygen generator, consisting of two small chambers formed in one case. These chambers are charged with a patented substance which, when in contact with the water vapor of the breath, gives off pure oxygen gas and forms a caustic alkali. The alkali in its turn takes up the carbonic acid gas of the respired air and forms an alkaline carbonate. In this way, as in various types of smoke helmet, the same air, purified and re-oxygenated, is used over and over again. The total weight of the whole outfit is 16 pounds. Folded up for stowage, it occupies a space of 12 inches by 12 inches by 15 inches. The dress can be put on without assistance in 30 seconds. When on it prevents a man from drowning, and in proof of this it may be said that it is now in everyday use under water with perfect success. Moreover, it acts as a life buoy, and actually raises its wearer to the surface. An additional device is also fitted to enable the wearer when he reaches the surface to inflate a flexible chamber which surrounds the jacket and thus to form a life belt. This provision is necessary, for the length of time the purifier will remain in action is limited, and when its efficiency is impaired the door in the helmet must be opened, which operation can be performed by the wearer, in order to admit fresh air. When this is done the helmet ceases to be buoyant. Other methods, such as the fitting of cork belts or chambers already filled with air, have been tried and abandoned, being found to be impracticable, owing to the necessity of employing heavy weights to keep the wearer down, and also by reason of the dangerous velocity with which he would rise to the surface on the removal of the weights.

At Portsmouth the British Admiralty have in use a huge water tank, at the bottom of which is erected a skeleton submarine boat, serving the purpose of permitting the men to exercise in the helmet described. The men having first been trained to put on the dress quickly are set to practice getting into and out of the air lock. They are afterward lowered in the air lock to the bottom of the tank, where they enter the submarine, and find their way to a ladder leading to the conning tower, the hatch of which they open. They then either float to the surface or return to the starting point, the operations being repeated until the officer in charge considers the men proficient. These arrangements have been designed to represent as nearly as possible the same conditions as would obtain in a submarine boat that had been flooded.

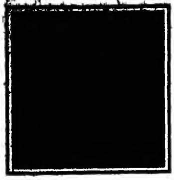
If the hole in the submarine be at the top, the water will gradually displace the whole of the air. If, however, the hole is below the top, then the water will only enter until the air, which cannot escape, has been compressed until its pressure is equal to that of the water outside. In the latter case there is no difficulty in getting at and putting on the helmet dress, since there is air inside the hull. In the former case, however, unless some special provision were made, this would not be so, and, accordingly, bulkheads are arranged to trap the air. The dresses are kept hanging up in readiness in the air pockets so formed. This does not in any way affect the habitability or efficiency of the vessel. It is [illegible]



By courtesy of Illustrated London News.

The boat having sunk to the bottom, air will be compressed either under the deck of the vessel itself or under the air-traps. Beneath the air-traps the men, having put on their special diving-helmets, sit, with their heads in the compressed air, until it is their turn to escape, either through the conning-tower or through the [illegible], and rise to the surface. In front of each waterproof jacket, attached to the diving-helmet, is a pocket containing a combined purifier and oxygen-generator, which enables the same air, purified and re-oxygenated, to be used again and again. The dress, which can be put on in thirty seconds, not only prevents the suffocation of the [illegible] acts as a lifebuoy. There are fitted to the air-traps air-supply pipes from the boat's compressed-air [illegible] that an extra pressure of air may be turned on when necessary. The drawing shows men, wearing [illegible] waiting under an air-trap in a submarine; men leaving the air-trap to ascend the conning-tower; a man leaving the conning tower to float to the surface, and a man escaping through the torpedo-hatch.

HOW MEN ESCAPE FROM A SUNKEN SUBMARINE.



# ARTIFICIAL RADIUM BATHS AND DRINKING WATER

BY DR. ALFRED GRADENWITZ

Until quite recently the curative effects of mineral waters were ascribed to the chemical substances held in solution. The lack of mineral solvents in some waters of remarkable therapeutic value could not be explained on this principle. Moreover for some unaccountable reason it was observed that most waters lost their healing properties when taken at some place distant from their source.

All these contradictory phenomena can now be plausibly explained by ascribing part if not all of the curative powe to radioactive s be anc s. In fa t early all mineral waters have been found to contain radioactive emanation. This emanation being an extremely unstable body most waters lose their activity in a few days so that the cura ive ag nt canno exert its action unless the water be administered as soon as possible after issuing from the ground. Only a few waters containing radioactive substances capable of giving off a co stant supply of e nana i n av been found to keep at least part of th ir a ivity for a y length of time.

This tra ing of effi a y o rad oa i y a ra y suggested the artificial control of rad a iv y so as to impart curative effects to ina wa o o crease the efficiency of natural sp ings. The i a of adding variable amounts of emanation has been car

ARTIFICIAL RADIUM BATHS AND DRINKING WATER.

# ALEXANDER GRAHAM BELL AND THE TELEPHONE

## THE STORY OF A GREAT INVENTION

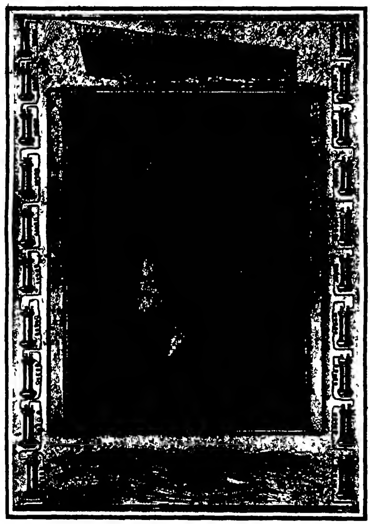
The telephone was first introduced to the public in 1876, and put to the first practical or commercial use in 1877 During that year was organized the first association or company to hold the patents The first companies which systematically exploited the business were formed in 1878, one for New England and one for the rest of the United States and Canada. These two companies succeeded to all the rights and property of the original association The capital represented $750,000 the value of the patents, and $100,000 in cash. Early in 1879 these two companies were consolidated into one company called The National Bell Telephone Company, the first company to attain any prominence The capital of this company was $850 000, deposited among 8 500 shares of $100 par value each The sum of $650,000 in shares was given, share for share, for the stock of the two old companies, and $200 000 in shares was left in the treasury This treasury stock was sold for the best price obtainable, as the money was required and yielded eventually $420,000 in cash The last 500 shares of this treasury stock sold for $600 each In the fall of 1879 a settlement was effected with the Western Union Telegraph Company, whereby the most formidable and powerful competitor was removed from the field Then it was that the stock boomed. The $100 shares, of which there were only 8,500, were quoted at one time at $1,000, although that price was probably never actually paid At the highest quotation, a total market value of all the shares of the company would have been $8,500,000 According to popular belief, twelve of the original investors have been credited with realizing if not more, at least as much as this, yet no dividends were paid by this company

Because of the rapid increase in business, more capital was required, hence in 1880 the American Bell Telephone Company was organized and the business of the National Bell Telephone Company transferred to it The shareholders of the National Bell Telephone Company were given for each share of their stock six shares of the new American Bell Telephone Company's stock At the same time, 8 500 shares of the treasury stock were sold at par In 1881 the first dividend was paid

The American Bell Telephone Company continued in business until 1899 during which time the capital stock had increased from $5 950,000 to $25,886,300 When the American Bell Telephone Company transferred its business to the American Telephone and Telegraph Company, there had been over $28,000,000 actual cash paid into the treasury of the company by the shareholders as against $25,886,300 capital outstanding During the time no stock dividend or a dividend of surplus in cash to pay for stock issued was paid The market price of the American Bell Telephone Company's shares during the year ranged above $200 a share, and the company was paying 15 per cent dividends yearly

The demands of the business required much larger capital than could be provided under the corporate powers of the American Bell Telephone Company Hence, the American Telephone and Telegraph Company was organized to operate the long-distance traffic, and to it the business was transferred in 1899 The dividends were put on a 7½ per cent basis, and were increased in 1906 to 8 per cent, at which rate they still continue. Since 1900 the stock of the American Telephone and Telegraph Company has been increased from time to time as the business called for money At the close of 1909 there were in the hands of the public $206,474,300

This tremendous industry is the fruit of Mr Alexander Graham Bell's indomitable and persevering work as a young man His story of the invention of the telephone is a story of patient endeavor and experiment, continued for years in the face of many difficulties. He approached the subject more or less an expert in speech, for both his father and grandfather had been teachers of articulation and the laws of speech, and he had himself been educated to follow in their footsteps. In boyhood he constructed a talking machine At the age of eighteen he made discoveries which he thought original concerning the part played in the production of vowel sounds by the resonance of the cavities of the mouth. It was not long before he learned that Helmholtz had not only made the same discoveries, but had produced the sounds of the vowels by combinations of tuning forks, operated by electro-magnets. In order to repeat Helmholtz's experiments, Bell began to study electricity In 1872 he constructed an experimental apparatus in which each transmitter consisted of a tuning fork with its prongs between the poles of an electro-magnet. Current was applied intermittently by means of a wire which was attached to one prong of the fork and alternately made and broke the contact with a cup of mercury as the fork vibrated. As the prongs of the fork were attracted by the magnet each time the current was applied, the fork was kept continuously vibrating and sounding By pressing a telegraph key, the intermittent current was sent through the line wire to the receiving instrument, which consisted of another electro-magnet and tuning fork If the receiving fork was exactly in unison with the transmitting fork it was also thrown into vibration, but if it was not in unison it remained silent, because the portional currents did



Copyright 1909 by Harris and Ewing

ALEXANDER GRAHAM BELL.

not reach it with the proper frequency to cause it to vibrate It was Bell's idea to use several transmitting forks of different pitches, and as many receiving forks of the same pitches. As each transmitter would affect only the particular receiver that was in unison with it, a number of telegraphic messages could thus be sent simultaneously over a single wire. Afterward Bell substituted for the tuning fork a steel plate or reed, with one end clamped and the free end very near the poles of the electro-magnet. The transmitting reed, like the tuning fork which it superseded, definitely made and broke contact, and thus made the current intermittent, and the receiving reed vibrated energetically only when it was in unison with the transmitting reed Still later Bell conceived the idea of polarizing or magnetizing each reed by clamping it to a pole of a permanent magnet, allowing its free end to project, as before, over the poles of the electro-magnet. He knew that the vibration of the magnetized reed would induce currents in the coils of the transmitting electro-magnet and that these currents, reaching the receiving electro-magnet through the line wire, would set the reed of the receiver into vibration if the two reeds were tuned to exact unison. This arrangement dispensed with the galvanic battery and the mercury circuit-breaker. The circuit was never broken and the current, instead of being intermittent, was undulatory, varying in intensity and direction in exact accordance with the motion of the transmitting reed. The two instruments were exactly alike, and either could be used as the transmitter. Several such pairs of instruments, of different pitches, could be employed, with a line wire connecting the two stations, and the plucking of any reed, at either station, would theoretically cause the reed of the same pitch, and that reed only, to "speak" at the other station, so that a number of messages could be transmitted simultaneously in each direction Bell, however, thought that the currents thus generated by the vibration of the reeds would be too feeble for practical use in multiple telegraphy and he therefore turned his attention to a system which included a battery and a mechanical circuit breaker

Meanwhile, in connection with his professional work, the instruction of deaf mutes and their teachers, Bell had been experimenting with the phonautograph, an instrument devised by Leon Scott for making visible records of the vibrations of sound. The short arm of a light wooden lever was attached to a membrane stretched over the small end of a funnel, and the long arm terminated in a bristle which touched a sheet of glass, covered with lamp-black, which was drawn along at a uniform speed. When a sound was uttered into the funnel the sound waves caused the membrane to vibrate and the bristle to trace on the smoked glass a sinuous curve, which represented the vibration so exactly that not only every pitch but every quality of voice, and each of the vowel sounds, produced its characteristic tracing. The principles of the phonautograph is almost identical with that of the phonograph Bell discovered defects in the instrument, and as he labored to remove them, it occurred to him that the best form of phonautograph would be an imitation of the human ear, in which the sound waves are likewise received by a membrane, the ear drum, and the vibrations are transmitted to the inner ear by a series of bone levers. Dr Blake, an aurist to whom Bell applied for precise information concerning the structure of the ear, suggested the employment of a real human ear instead of an imitation An anatomical specimen was prepared, with a fine straw attached to one of the bone levers to serve as a writing point, and Bell experimented with it in 1874, while he was still working with his reeds and electro-magnets

Another possibility had occurred to him. He knew that when a vowel sound is sung into an open piano all the strings that correspond to the overtones, which give the sound its vowel quality, as well as the string corresponding to the fundamental tone, are set into vibration, so that the piano repeats the particular vowel uttered. In like manner, the transmitting reeds, if sufficiently numerous, might take up from the air the component simple vibrations of a vowel sound and transmit them by means of the electro-magnets and the line wire to the receiving reeds, which would reproduce the vowel sound at the distant station Bell also considered the possibility of employing, at each station, one large electro-magnet instead of many small ones, in connection with all of the reeds, and thus combining the elementary electrical vibrations, corresponding to the components of the aerial sound waves, in the coil of the electro-magnet, instead of in the line wire. "In this way," the inventor has said, "I realised in the summer of 1874 the conception of a speaking telephone, and the apparatus is the first form of speaking telephone that occurred to my mind." But it seemed impracticable to construct an apparatus with a sufficient number of reeds, and so that "harp" telephone was never realized. Then it occurred to Bell that the resultant electrical effect in the coil of the electro-magnet might be produced by a single reed, if this reed could be formed to move in accordance with the resultant sonorous vibration. While studying this problem he was experimenting with the phonautograph made from a human ear. He was struck with the lightness of the ear drum in comparison with the weight of the bones moved by it, and it occurred to him that a larger [illegible] might [illegible] of steel in the desired manner. # A MOTION APPARATUS FOR AMATEURS

## AN INGENIOUS FRENCH INVENTION

The production of photographs of moving objects has hitherto been denied to amateurs, for various reasons. It requires complicated and costly apparatus and delicate manipulations which cannot be performed without special appliances.

A simple apparatus, called the Cinephote, has been devised to obviate these difficulties and to put motion photography within the power of every amateur photographer, at least to the extent of producing animated portraits of his friends and his children, for the Cinephote does not pretend to vie with the elaborate apparatus by which thousands of instantaneous photographs of a long and complex scene are impressed on hundreds of feet of film.

small perforations, causes the disk to rotate intermittently, pausing after each advance long enough for a single exposure. At the same time the shutter is automatically caused to open when the disk stops and to close when it resumes its rotary movement For the disk containing 24 pictures arranged in a circle, the bearing is fixed at the center of the plateholder, but for the disk with 75 spirally arranged pictures, the bearing is free to move in a vertical slide end, as the reciprocating pin engages successively with the spirally arranged perforations, the disk is displaced in such a manner that each picture is made in its proper place in the spiral curve In either case the movement of the mechanism is automatically arrested when

work and essentially similar to the mechanism employed in making the negatives But, as only a very fleeting illusion is thus produced by the disks which contain 24 pictures, there is provided, for these disks alone, another apparatus which can be turned by hand, slowly and for an indefinite time, showing the pictures repeatedly in their proper order A third form of apparatus is furnished for the purpose of projecting the pictures on a screen with a lantern

A writer in a contemporary refers to numerous failures of cast iron fittings which were, however of the usual run of commercial extra heavy fittings of which neither the metal nor the thickness were sufficiently

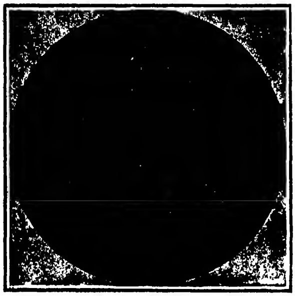

Fig. 1.—Disk with 24 pictures.

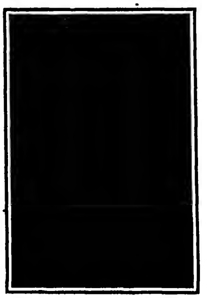

Fig. 2.—Watching the motion pictures.

Fig. 5.—Disk with 75 pictures.

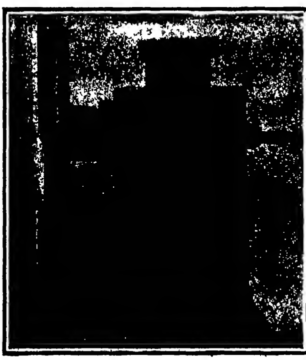

Fig. 4.—Apparatus for projecting the motion pictures.

Fig. 3.—Cinephote camera and plateholder.

A MOTION APPARATUS FOR AMATEURS.

The Cinephote comprises two distinct pieces of apparatus: one for making the pictures, the other for exhibiting them in such a manner as to give the illusion of movement. Both of these devices work automatically, by means of very simple mechanism The negatives, which are either 24 or 75 in number, are made on a circular sensitized plate, on which the 24 pictures are arranged in the form of a circle, while the 75 pictures are arranged spirally, as the accompanying illustrations show. In either case, the disk is perforated with small holes, equal in number to the pictures, and distributed at equal angular distances along the same curve—circle or spiral. By means of a larger hole at its center, and a corresponding peg, or bearing, in the plateholder, the disk is secured in the latter in such a manner that it can turn freely about its axis. The pressing of a button then releases a pin, to which a [illegible] horizontal movement is imparted by [illegible] and which, engaging successively with the

the entire series of photographs has been made, so that double exposures are prevented.

The lens of the Cinephote is either a "Graphor," which is corrected for astigmatism, and can be used with a stop of F/6 and produces satisfactory outdoor views in most weather conditions, or a "Eurygraph" anastigmat, which is very well corrected for spherical and chromatic aberration and gives perfect definition with a stop of F/3.5

As there is no rigid connection between the disk and the mechanism, either single or double plateholders, or even a magazine camera, can be employed

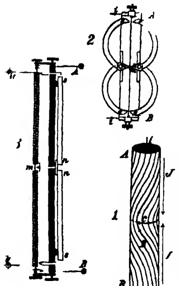
The negatives are developed in the ordinary manner, with the aid of a specially constructed printing frame, and [illegible] are made [illegible] which have perforations corresponding to those of the negatives. The moving scenes are reproduced and presented to the eye (assisted by a magnifying lens) by means of an automatic mechanism driven by clock-

good The growth of cast iron under repeated heating is discussed and reference is made to Outerbridge's work. Steel fittings have also failed, within the author's experience only four out of twenty five steel gate valves, 6 inches, 8 inches, and 10 inches in diameter, were fairly tight after one year's service A thoroughly sound steel casting can withstand highly superheated steam, which does not initiate defects but rapidly develops them Gun iron is high grade cast iron having a tensile strength of 30,000 pounds or more, and is adapted for 180 pounds of steam with 300 deg F superheat Analysis of various specimens of iron which failed under 250 deg superheat are given, but the following successfully withstood 300 deg. superheat for four years Silicon, 1 72 per cent, sulphur, 0 085 per cent, phosphorus 0 89 per cent, manganese, 0 48; total carbon, 2 45, combined carbon, 0.17 Low silicon, phosphorus, and carbon characterize it.

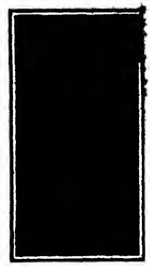
# AN INGENIOUS TORSIONAL WAVE DETECTOR

BY THE PARIS CORRESPONDENT OF THE SCIENTIFIC AMERICAN

Prof. A. G. Rossi of the Royal Polytechnic Institute of Turin has devised a new form of detector for use in wireless telegraphy which is of special interest because of the novel principle it employs. He uses the property known as magneto-striction found in iron or nickel wires. A fine iron wire stretched in a magnetic field is found to lengthen at first and then shorten according to the strength of the field, the value effect being about 1/400000th of the length of the wire. The inventor sought to increase this effect and to apply it to a detector for waves. The principle of the apparatus is shown in Fig. 1. A fine iron wire is stretched in a vertical position between two fixed points *A B*. Two constant magnetic fields formed by two equal bar magnets magnetize the wire in two halves in the opposite sense with the intensity *J J* and longitudinally as shown by the arrows. At the same time a current is sent through the wire from *i* to *i* and this gives a circular magnetization to the wire with an intensity. The result of the combined magnetic fields will be a magnetization of helical form *I*. Owing to the effect of magneto-striction the wire will have a torsion represented at *C* in the direction of the arrow, this being what is known as the Wiedemann torsion effect. Leaving the longitudinal field as it is if we reverse the current in the wire the torsion effect will be also reversed. When we send an alternating current through the wire we have a strong effect of vibration as the torsion is also alternating in its sense. A mirror placed at the middle of the wire is made to reflect a beam of light on a screen and the spread of the beam shows the amplitude of the vibration. The effect is much stronger when the period of the alternating current is of the same value as the normal vibration rate of the wire, and we have a much longer line of light on the screen. The wire is of about 0.02 millimeter diameter, and is held under tension between two light springs mounted on an insulating plate. Fig. 2 shows the arrangement, and the springs are coupled to the binding posts *A B*. Near the ends and at the middle of the wire project three iron points which come from the bar magnets *n s n s* so as to guide the magnetic flux into the wire. This latter is stretched inside a glass tube of small diameter leaving a gap at the center for the mirror *m*. A spiral of insulated copper wire is wrapped about the glass tubes with the two halves coiled inversely and the current comes from *a* and *b* into the wire. The copper spiral is designed to receive the waves from the antenna and it acts to modify the effect which we have seen above to be given by the combination of the alternating current and the bar magnets in the wire. When no waves are received we have a constant torsion effect in the wire, that is a constant rate of vibration. When on the contrary the wave effect occurs in the copper spiral the rate of the vibration is modified and the line of light on the screen is changed. The terminals *a b* are connected to a pair of vertical antenna wires which are insulated from ground. All the rest of the apparatus is held insulated on a glass tube support 5 feet from the floor. Light for the beam is given by a Nernst lamp and the same alternating current circuit is used for exciting the wire using the proper means to secure a very small current through the wire. The copper spiral is joined at the top to the antenna and at the bottom to ground. With such an arrangement the instrument shows the effect of waves received from a distant station and we notice variations in the beam of light due to this cause. It is designed especially to be used for receiving signals formed by a succession of waves, such waves to follow each other in series so as to form periods of low frequency. The frequency is first adjusted so as to be the same as that of the vibrating wire. Besides the tuning of the high frequency waves, this allows us to use a second, or local tuning of the low period waves. It should be remarked that Prof. Rossi's instrument transforms directly an electric vibration of low frequency into a mechanical vibration and contrary to other detectors, there is no transformation of energy between the effect of the name and the registered optical indication. It is thus extremely sensitive. To have a permanent record of the signals, the author proposes the use of a photographic band descending in front of the beam and as the variations of the latter are sidewise, we would have a set of wave-like signals printed on the band. By using a selenium cell which is lighted by the beam we could work a Morse register with the instrument, provided a strong enough light is reflected by the mirror on the cell. Owing to the sensitiveness of the instrument there is no doubt that it can be used with a much less expenditure of power at the sending station. On the other hand it simplifies the apparatus which is needed at the receiving station. An alternating current generator is not required in this case, but a simple vibrator will give the needed impulses for exciting the stretched wire.



How the torsional effect is produced



A detector which transforms electrical wave trains into mechanical vibrations.

# THE HEIGHT OF THE ANTARCTIC CONTINENT

BY WALTER LANGFORD

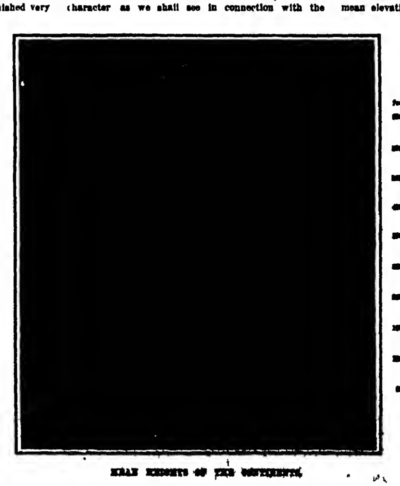
Our knowledge of the Antarctic continent is daily becoming more precise. Soon after Shackleton's memorable dash toward the South Pole had furnished very important data in regard to the interior of the continent, Charcot's voyage supplied valuable additions to our knowledge of the boundaries of this vast territory. The French expedition succeeded in surveying accurately a great many miles of coast line that had previously been entirely unknown or only conjecturally laid down.

The results of these expeditions prove that the mass of land accumulated about the South Pole is even greater in comparison with the other continents than had previously been supposed. The elements involved in this comparison include an estimate of area and a determination of the heights of the mountain masses. Both of these elements require exact and comprehensive surveys. The problem was first attacked by Humboldt at an epoch when our knowledge of the earth was very incomplete. Hence Humboldt's estimates of the mean elevations of the known continents above the sea level are far too low. This mean elevation is the height of a fictitious plateau obtained by distributing the mass of the continent uniformly over its surface, i. e. it is the quotient obtained by dividing the volume by the area. Humboldt's estimates of the mean elevations of continents are: Europe 6?? feet, North America 748 feet, South America 1151 feet, Asia 1151 feet, entire known land surface of the globe 1004 feet. Except in the case of Europe these values differ enormously from the more recent estimates given below. This discordance shows the necessity of thorough exploration and accurate surveys although a general estimate can be obtained from elements of a totally different character as we shall see in connection with the Antarctic continent. Kruemmel, who was the next after Humboldt to attack the problem, estimated the mean elevation of the entire known land surface of the globe at 1443 feet, a value which was still far below the truth. The later estimate of Lapparent, based on more complete data, was 2,000 feet, or more, while the more recent estimates of Murray, Penck, Lupan and De Lillo are still higher. Murray's values as revised by Penck are: Europe 918 feet, Australia 918 feet, North America, 1,968 feet, South America, 2,066 feet, Africa 2,132 feet, Asia 3,116 feet, general land surface, 2,312 feet. From these values which appear to be very nearly correct, the total volume of the continental masses is computed to be about twenty-four million cubic miles.

All of these estimates relate only to those parts of the world that were known at the epochs when the various estimates were made. The recent Antarctic explorations have entirely changed the face of the problem and have raised the Antarctic continent to the first place which was formerly occupied by Asia. The exact and extensive knowledge which we now possess in regard to the other continents is still lacking in the case of the Antarctic, of which we know only the few points that have been reached by the expeditions.

Meinardus has endeavored to determine the height of the Antarctic continent from meteorological data. With the distribution of atmospheric pressure and the [illegible] of [illegible] air between [illegible]

[illegible]



MEAN HEIGHTS OF THE CONTINENTS

# CURIOSITIES OF SCIENCE AND INVENTION

### MOVING A TOWN BY RAIL.

Pictured herewith is a trainload of houses on the Weatherford, Mineral Wells & Northwestern Railway in Texas. There are five flat cars loaded with miners' cottages of two rooms each, each room being 12 by 14 by 8 feet. Extreme height above the car is 15 feet 4 inches. In addition there are two cars containing the lean-to kitchens, and two cars that carry other wreckage of the coal-mining town of Rock Creek, Texas, whose mines were abandoned. The train was moved successfully at the rate of 15 miles per hour, and around a number of six-degree curves having the outer rail elevated four inches.

A TRAINLOAD OF MINERS' COTTAGES.

### WOODEN FRAMES FOR AIRSHIPS.

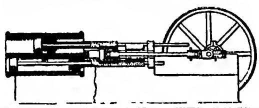
When the Zeppelin balloon was destroyed in a thunder storm two years ago it was asserted that a static discharge of electricity from the metallic frame of the balloon had ignited the gas. To obviate such an accident in the future, a German inventor has devised a balloon having a wooden frame, which he claims is not only lighter than aluminium, but is stronger as well. A frame thus constructed was exhibited at the Frankfort Exposition last summer, and proved quite an attraction. The accompanying photographs show how the frame is made up in a network of wooden strips which is very strong and yet possesses a considerable degree of flexibility. The model illustrated is 65 feet long and 8 feet in diameter. The meshes of the network are much smaller than in the Zeppelin type of balloon, using aluminium framework. Accordingly, the wooden frame makes a more efficient support for the envelope of the balloon when the gas is expanded by the heat of the sun. Another advantage of the wooden frame is the fact that it can be repaired anywhere, whereas aluminium can be worked only with special apparatus and by an experienced workman. The wooden frame is not affected by heat or cold, and may be rendered waterproof by coating it with a suitable varnish.

A BALLOON FRAME FORMED OF WOODEN STRIPS.

[illegible] INTO THE WOODEN BALLOON FRAME.

### ENGINE WITH HEADLESS CYLINDERS.

In order to produce a completely-balanced engine, an inventor has recently adopted the unique plan of providing the engine cylinders with two pistons each. The steam enters between the two pistons, separating them. This renders the cylinder heads useless, for there is no reaction against them. One of the pistons is provided with a hollow piston rod to receive the rod of the other piston. The engine shaft is provided with two cranks at right angles to each other, which are respectively connected to the two piston rods. Thus a forward and backward impulse is given simultaneously by the steam entering one cylinder, and there is an equal distribution of the load. When the pistons reach the end of their stroke, steam is admitted to a second cylinder of the same type, which repeats the operation while the first cylinder exhausts. There are no jolts, strains or vibrations, as the forces are entirely absorbed in motion. The ends of the cylinders are preferably closed by suitable doors, to prevent dust or other extraneous matter from entering and choking or clogging the working parts. These doors are shown open in the accompanying photograph. The model illustrated has shown remarkably high efficiency, and is so perfectly balanced that it will run smoothly on the flimsiest of supports.

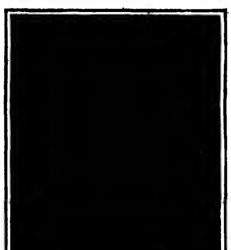


SECTIONAL VIEW SHOWING CROSS CONNECTED PISTONS.

A HEADLESS-CYLINDER BALANCED ENGINE.

### A NOVEL AUTOMATICALLY ADJUSTABLE ORGAN BLOWER.

A novel method of adapting electric motive power to organ blowing is shown in the accompanying engraving. The mechanism comprises an accurately turned hemisphere of aluminium driven by a small electric motor fixed to a bracket swinging horizontally on a vertical spindle. The hemisphere drives by friction an ordinary bicycle wheel fitted with a pneumatic tire, as shown in the illustration. There are the usual cycle chain and sprocket gear, for still further reducing the speed, and the final chain wheel transmits reciprocating motion to the bellows handle by means of a crank. There is no slip between aluminium hemisphere and the tire, owing to the elasticity of the air cushion, and as they are constantly in contact there is no wear. This ingenious little machine will blow a 16-stop or larger organ silently and with very high efficiency. It requires no attention, and current sufficient to run the motor is obtained by connection with an electric lamp socket. As it is practically silent and occupies a surface of only 45 by 16 inches and is 23 inches in height, it can be placed on the floor beside the instrument. The speed of the motor is constant, but automatic control of the pumping is provided by a chain connection between the swinging bracket and organ reservoir or bellows. By means of this chain the motor and hemisphere may be drawn through an arc of 90 degrees into the position of full organ, while a spiral spring returns them to the neutral position, as shown in the illustration. The rising and falling of the reservoir thus cause the speed of the bellows handle to vary from zero to maximum, and keep the bellows full automatically.



NOVEL ELECTRIC ORGAN BLOWER.

The speed is regulated by a swinging hemispherical friction wheel.

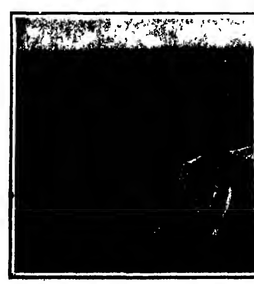
### A NOVEL PADDLE FLYING MACHINE.

The peculiar flying machine illustrated herewith was one of the novelties at the Olympia Aero Show held recently in London. It is the invention of Messrs. Wyllie and Ottino, and consists of a large number of small planes arranged in an endless band and driven somewhat after the manner of a tread mill, the idea being that as these planes move along from one end of the machine to the other at a rapid rate they produce a lifting effect owing to the slight angle to the horizontal at which they are set. As they move around at one end in passing from the bottom to the top they are at an angle to the horizontal and still produce a lift, while as they descend at the other end their downward movement produces a lifting effect. The machine was exhibited without a motor but this fact did not detract from its novelty. The idea of the moving planes is that the flying machine will lift itself directly in the air and that no forward motion over the ground will be required.

FLYING MACHINE WITH A TRAVELING CHAIN OF LIFTING PLANES.

### A SERPENTINE WHARF.

One of the longest wharves in the world, almost a mile in length, or to be exact, 4,700 feet, is at Port Los Angeles, Cal. It extends into the Pacific in a long serpentine curve. The reason for this construction is that it offers better resistance to the strong currents and the buffetings of the waves than if it were perfectly straight. Until the nearby harbor of San Pedro was developed by the Federal government, the big wharf at Port Los Angeles was a very busy place, but of late it is comparatively seldom used except by the Japanese fishermen, who have formed a colony along the adjacent beach.



A SERPENTINE WHARF NEARLY A MILE IN LENGTH.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

BELT.—G. W. REAM and P. E. GREEN, Butte, Mont. In this case the object of the invention is to provide an extensible belt, which may be folded to form a belt of ordinary width, or unfolded to make a belt of varying capacity, in accordance with the contents to be contained therein, and which in any position will be firmly secured together.

### Electrical Devices.

LEVER-CHECK FOR ELECTRIC CONTROLLERS.—J. THOMAS, New York, N. Y. This invention refers to a device to be used as an attachment for controllers such as are mounted on electric cars for controlling the operation of the motors. An object is to improve the construction of the pawl so as to render it more efficient. Further, to improve the means for resiliently constraining the pawl arm toward the segment, and to improve the device in other details.

### Of Interest to Farmers.

FEEDING ATTACHMENT FOR FANNING MILLS.—H. DYKSTRA, Spring Valley Township, S. D. The object here is to provide an attachment which can be removably mounted upon the fanning mill, which is adapted to feed fanning mills of different sizes and types by means of which grain and the like can be fed into the mill continuously and evenly, in which the rate of feeding can be exactly controlled, which is adapted for use with fine as well as with coarse grain, and which is simple to operate.

CLEVIS.—G. H. JOHNSON, Cimarron, New Mex. This invention is an improvement in the construction of the ordinary U-shaped clevis used on plows, cultivators, and harrows for the attachment of draft appliances. The head of the bolt is prevented from contact with other objects, which is very objectionable in clevises of the ordinary construction. In order to protect the head of the fastening device from contact with other objects, it may be arranged in a socket, so that when in locking position the head does not project above the clevis.

WATERING-TROUGH.—T. C. THRASHOOM, Irwin, Iowa. The aim of the inventor is to provide a simple, strong and durable watering trough, in which the flow of water is automatically regulated, so that the water will not exceed a certain predetermined height in the trough, and in which the flow of the water is positively controlled by the action of the float.

### Of General Interest.

GLASS-DRAWING FURNACE.—I. J. BALSTON and J. BARNES, Kane, Pa. An object in this instance is to provide a new type of furnace, readily accessible, and which will permit clean and uniform cylinders to be drawn therefrom. Further, to provide a glass-drawing furnace with means for protecting a plurality of baths therein and with means for framing and protecting a clean drawing surface.

CLOSURE.—C. D. LOVE, Newark, N. J. The purpose of the improvement is to provide a closure for use on bottles and other packages and arranged to insure perfect hermetic sealing of the package, by the use of a spring interposed between the cap and the closing disk and bearing annularly on the latter at a point opposite to the support for the closing disk.

WRITING TABLET.—H. C. KELLY, Minneapolis, Minn. Among the principal objects in view in this invention are: to provide an order book having a cover wherein is provided a pocket to contain envelops adapted for mailing the order sheets from which the said book is constructed, and to provide a form of construction which is durable, simple and economical.

ADJUSTABLE RACK REVERSIBLE DEVELOPING TANK.—P. Y. HOWE, Yonkers, N. Y. The purpose here is to produce a rack for holding the plates within the reversible tank, and to provide a construction for the rack which will enable plates of different sizes to be securely held. The rack involves a construction which permits the plates to descend to the bottom of the tank whether it is held in its upright or in its reverse position.

PASTE-BOX.—O. DARMAN, Stroudsburg, Pa. The purpose of the inventor is to so construct the brush holder that the brush will be automatically raised from a substantially horizontal position to an inclined position, as the cover of the box is raised. This brings the handle of the brush to an elevated position above the top of the box so that it may be readily grasped ready for use.

DISPLAY APPARATUS.—E. F. CANNON, Portland, Ore. The object here is to provide an apparatus for exhibiting goods or wares, in which the goods are arranged upon carriages which travel successively and continuously in a plurality of directions and thus show the goods to the best advantage and from different sides, and in which the carriages are movably supported upon the floor, which, at the same time serves to conceal the mechanism for actuating the carriages.

ANIMAL TRAP.—P. J. KOTTUM, Sacred Heart, Minn. This trap is of the class that chokes the captured animal to death, and the object is to provide a trap of this character that is simple, strong, easy to produce, and which, when assembled presents a compact trap that is very effective and kills the animal without injuring its pelt.

### Household Utilities.

STAND-BOILER.—W. SHERWOOD, New York, N. Y. The object of the invention is to provide a boiler, arranged to direct the hot water coming from the heater or water back of the range or furnace, into the top of the boiler, to prevent this hot water from being reduced in temperature by contact with the cold water entering the boiler shell from the water main or other supply at or near the lower end of the boiler shell.

CLOTHES LINE HOLDER.—A. HEINEMANN, New York, N. Y. The invention relates to holders of the kind especially adapted for use in connection with buildings, the more particular purpose being to provide a holder having an arm mounted upon a window jam, or the like, and adapted to swing for the purpose of affecting the condition of the clothes-line which is practically supported by the arm.

ELECTRIC COOK STOVE.—F. H. ZATOSK, Detroit, Mich. This cooker is more or less analogous to a so-called "fireless cooker," and the aim is to fit within the same a number of electrically operated heating units for supplying heat to the stove. Heat is regulated by a proper distribution of the heating units, by cutting out a suitable amount of the resistance offered by the heating units themselves.

CHAIR.—W. S. PHILLIPS, Cameron, W. Va. The invention is an improvement in chairs, and the object of the improvement is to provide a chair which will fold up under a table or other support out of the way, when not in use, by means of a spring and which may be easily drawn out into position when required, and will be locked in such position by its own weight.

### Machines and Mechanical Devices.

LOOSE-LEAF BINDER.—T. BEARD-DIMSEY, North Sydney, New South Wales, Australia. The object of the inventor is to provide a mechanism for the binding plates, which is arranged so as not to diminish the capacity of the case or frame or be injured when the clamping plates are fully moved apart and which extends longitudinally of the case to one end thereof at a point conveniently accessible for operation.

TIPPING FURNACE MIXER, ETC.—J. L. KLINDWORTH, Bellevue, Pa. The improvement is designed to provide means of an efficient character for protecting the actuating screw from contact with dirt, molten metal, or other foreign matter, and further, to provide means of novel character for relieving the actuating screw and nut from vertical and lateral thrust and pressure.

AIRSHIP.—L. ANTHEITER, Jersey City, N. J. The object of the inventor is to provide an airship or aeronef arranged to provide a large sustaining surface, and to permit of conveniently raising, lowering, propelling and steering the ship in any desired direction. The suspended car is preferably in the form of a boat capable of floating on the water if required, and to allow the aerial vessel to again rise from the water.

### Prime Movers and Their Accessories.

CARBURETER.—G. E. COOK, New York, N. Y. One object in this case is to provide means whereby the opening of the throttle valve to bring an increased number of jets into operation, also operates to permit of an automatic dilution of the explosive charge in accordance with the suction pressure and speed of the engine.

ELASTIC FLUID MOTOR.—J. L. SHIRLEY, 2a Bucareli No. 800, City of Mexico, Mexico. This invention consists in an elastic fluid motor having a rotating distributing valve which is adapted by its rotation to supply working fluid to one or more cylinders and exhaust the working fluid therefrom in the proper sequence. It further consists in the improved distributing valve and valve gear.

### Railways and Their Accessories.

STAND-PIPE FOR RAILWAY WATER SUPPLY.—P. H. KNIGHT, St. Joseph, Mo. The principal objects here are: to provide a construction of a pipe wherein the operative parts are constructed in a form light, strong and durable; to provide a construction wherein the usual splashing or loss of water incident to the operation of drawing same at the water stations is eliminated; to provide an operating mechanism which is compact, certain and easy of manipulation, and to provide a construction adapted to compensate the disadjustment incident to employment in the ordinary service.

### Pertaining to Vehicles.

CAR FENDER.—C. P. BRONSON, Corning, New York. The invention is an improvement in fenders, more especially designed for automobiles, and has in view a comparatively light fender, which when in normal position, is compactly arranged and projects a relatively small distance beyond the front of the vehicle, and when striking a body, is automatically forwardly extended to receive and support the object struck.

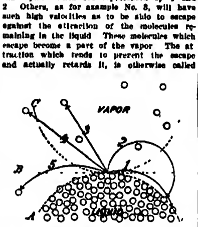
NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th, 1909, or will be sent by mail on request.

(12240) J. F. B. writes: In your issue of April 16th C. F. L. inquires for an explanation of the connection between curvature of surface and vapor pressure. The following is abbreviated from Millikan's "Mechanics, Molecular Physics and Heat," price $1.65, and Watson's "Physics," price $3.50, together with a few wrinkles of my own. All matter is conceived by physicists to be composed of molecules whose shape is not definitely known. One of the most characteristic differences between a liquid and its vapor is that the molecules are close together in the liquid and farther apart in the vapor, somewhat as suggested by the diagram. A very essential part of this molecular theory is that the molecules are in motion, and because there is no friction between them, their motion does not die down because of collisions, merely rebounding according to the laws of perfectly elastic impact. Hence a drop of water has more of an exact boundary than a pile of sand or marbles if reduced to corresponding dimensions. A mathematical treatment will show that the foregoing hypotheses lead to another, namely, that the molecules could not all have the same velocity even though initially endowed with the same velocity. Whence we come to the conclusion that molecules are continually arriving at the surface of the drop with varying speeds and directions. Some molecules will have such low speeds or such unfortunate directions that they will be attracted back into the liquid. Such are represented by 1 and 2. Others, as for example No. 3, will have such high velocities as to be able to escape against the attraction of the molecules remaining in the liquid. These molecules which escape become a part of the vapor. The attraction which tends to prevent the escape and actually retards it, is otherwise called



cohesion, though merely gravitation at close range. Now let us consider the liquid at the different curvatures, as $A$, $B$, and $C$. Molecules 1 and 2 would return to the liquid in any one of the three cases, while molecule 3 would probably escape at the same time. Molecule 4 however would return to the liquid if the surface were at $C$, but would escape if it were at $A$ or $B$, and molecule 5 would escape if the surface were at $A$ but would return to the liquid if the surface were flat or concave. Therefore we feel at liberty to make the following statements: (1) That more molecules can escape per second from a convex surface than from a flat one, and (2) more from a flat one than from one that is concave. Since the vapor pressure at a given temperature for a given liquid depends on the number of molecules that can leave per second, we see that the vapor pressure of a convex liquid surface is greater than one that is flat or concave, and that the more convex the greater the vapor pressure. These conclusions have an interesting connection in the formation of rain. The microscopic drops constituting the clouds are not in all probability all of the same size, so that the small ones would have a tendency to evaporate and the vapor condense on the larger ones with a much weaker vapor pressure. Thus the drops grow until large enough to fall rapidly. After falling becomes quite rapid it is probable that collision with smaller drops is more efficient in increasing their size.

(12241) B. L. C. asks: Does air or other gas expand when heated in a closed cylinder sufficiently for the pressure to be increased, and if not, how is the pressure increased? A. Air cannot expand in a closed cylinder, if heated. The pressure rises because of the increase of heat energy which would cause expansion if the air were under only normal pressure and were heated. All gases act nearly alike in this respect. The expansion for a rise of temperature from 0 deg. C. to 1 deg. C. is 1/273, and so on for higher temperatures. Kent in his "Mechanical Engineer's Pocket Book" gives a table of pressures and temperatures up to 300 pounds pressure. At 300 pounds pressure the temperature of air not cooled is 372 deg. F.

## NEW BOOKS, ETC.

THE ADVANCEMENT OF INDUSTRY. Being a Study of Certain Manufacturing Industries in India, With Suggestions for Their Development. By Henry Hemantakumar Ghosh. Calcutta, India: R. Cambray & Co., 1910. 8vo.; 222 pp.

The early years of the present century have witnessed the birth of a new era in India, which is likely to be remembered as much for the industrial awakening it has caused, as for the political aspirations it has aroused in the people. The author attempts to make some suggestions for the improvement of native industries. The illustrations are awful; we have almost never seen such cuts in any printed book. It is not likely that the book will be of much interest to American readers.

SOLID BITUMENS. Their Physical and Chemical Properties and Chemical Analysis. Together with a Treatise on the Chemical Technology of Bituminous Pavements. By S. F. Peckham, A.M. New York and Chicago: Myron C. Clark Publishing Company, 1909. 8vo., 324 pp. Price, $5.

The literature of bitumens is rather limited, therefore the present volume will prove of value. The titles of the chapters are as follows: Geographical Distribution of Bitumens, Origin of Bitumens, The Classification of Bituminous Substances, The Derivation of Natural Solid Bitumens, The Derivation of Bituminous Rocks, The Derivation of Artificial Solid Bitumens, General Considerations Concerning the Chemistry of Solid Bitumens, Boussingault's Memoir Upon the Composition of Bitumens; The Use of the Words, Petrolene, Asphaltene, etc., The Ultimate Analysis of Solid Bitumens; The Proximate Analysis of Solid Bitumens, The Technical Analysis of Solid Bitumens, Special Chemical and Physical Methods of Analysis by Which Solid Bitumens May be Recognized and Distinguished, Miscellaneous Methods Applied to Street Mixtures and Surfaces, Bituminous Paving Blocks, Bituminous Concrete, Wood Paving Blocks, Cements, Cement Mortars and Concrete, etc., Specific Gravity, etc., Historical Introduction, A Modern Street, Bitulithic Streets, The Oiled Roads and Streets of the Pacific Coast, Asphalt Blocks, Wood Blocks, Conclusions.

PATTERN MAKING. By H. Willard. Chicago: Popular Mechanics Company, 1910. 12mo., 214 pp. Price, $1.

This book contains chapters on core making and molding. It is written by a practical pattern maker of long years' experience. The information given appears to be of a very practical nature, and the book will undoubtedly prove of value.

PRACTICE AND THEORY OF THE INJECTOR. By Strickland L. Kneass, C.E. New York: John Wiley & Sons, 1910. 8vo., 175 pp. Price, $1.50.

Since the publication of the second edition, there have been marked changes in the construction of locomotives which have reacted upon the method of feeding boilers and consequently upon injector design. Many of the heavy articulated types have no available space within the cab for an injector of the required capacity, so that the trend is again toward the non-lifting form. Further, motive power officials are recognizing the advantage of utilizing waste products for heating the feed water, and purifying it of scale-bearing salts, and are giving more attention to the details of boiler feeding accessories which make for economy of operation as well as for the safety of passenger and employee. Owing to the development of the steam turbine, a large amount of experimental work has appeared in technical journals in connection with the flow of steam. It is gratifying to the author that these late investigators confirm his experimental work, first published in 1891, extracts from which are given in the text.

MOSQUITO OR MAN, THE CONQUEST OF THE TROPICAL WORLD. By Sir Rupert W. Boyce, M.B., F.R.S. New York: E. P. Dutton & Co., 1909. 8vo.; 267 pp. Price, $3.50 net.

The author has purposely selected the title "Mosquito or Man" in his endeavor to epitomise in one the tropical-medical movement which is now spreading all over the civilized world. Large numbers of well-equipped medical men have been sent to the tropics. Vast mines of literature dealing with tropical diseases have been distributed, and the public has been steadily educated to understand that it is not impossible to make the tropics healthy. The author shows that the three great diseases of the tropics which were the greatest enemies that mankind has ever had to contend with, namely, malaria, yellow fever, and the sleeping sickness, are now fully in hand. The tropical world is unfolding once more to those who do not now dread the deadly hand of death as did the men of old. The book is admirably printed and is beautifully illustrated.

THE COPPER HANDBOOK. A Manual of the Copper Industry of the World. By Horace J. Stevens. Houghton, Mich., 1909. 8vo.; 1,[illegible] pp.

[illegible]

per properties of the world. The copper mines in various countries are dealt with, and there is an excellent glossary There are also chapters on the uses of copper; substitutes for copper; brands and grades of copper, alloys of copper; electro-metallurgy of copper, pyro-metallurgy of copper; hydro-metallurgy of copper; milling and concentrating of copper, smelting of copper; chemistry and mineralogy of copper, geology of copper, etc.

AMERICAN GAS PRODUCER PRACTICE AND INDUSTRIAL GAS ENGINEERING. By Nisbet Latta. New York: D Van Nostrand Company, 1910 4to., 439 pp Price, $6 net.

Producer gas is gaining in favor each year in the United States, and it will take some time before there is an adequate literature relating to it The present volume goes a long way toward filling a vacant niche. The author is thoroughly acquainted with his subject, as is shown by the handsome piece of book-making before us. The chapters deal with Producer Operation, Cleaning the Gas, Works Details, Producer Types, Moving Gases; Solid Fuels, Physical Properties of Gases, Chemical Properties of Gases, Gas Analysis, Gas Power, Gas Engines, Industrial Gas Applications, Furnaces and Kilns, Burning Lime and Cement, Pre-Heating Air, Doherty Combustion Economiser, Combustion in Furnaces, Heat, Temperature, Radiation and Conduction, etc. The book has 247 illustrations.

PRACTICAL DYNAMO BUILDING FOR AMATEURS. By Arthur J. Weed. New York Norman W Henley Publishing Company, 1910 12mo.; 83 pp., 64 illustrations Price, $1 in cloth, 50 cents in paper

Practical directions are given in this work for the construction of a small dynamo of the type particularly adapted for use in manual training schools and State colleges The dynamo has a capacity of 50 watts, and weighs but a little over five pounds, so that it is of convenient size for use in a class room or in a lecture hall, where it can be passed around for purposes of illustration. This little machine has been successfully used for furnishing current to spark coils. In a large New England wire mill a dozen of these machines have been used as motors for spooling fine copper wire.

THE BOY AVIATORS IN NICARAGUA. By Captain Wilbur Lawton New York Hurst & Co, 1910 12mo; 336 pp Price, 35 cents.

This book is nothing if not up-to-date. It takes up a most exciting story of a most impossible nature, in which two boys who have built an aeroplane become involved in the revolution of Nicaragua Their exciting adventures with a general of the Nicaraguan forces who is bent on their destruction, and also that of a newspaper correspondent, should give boy readers many a thrill.

## Legal Notices

# INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending May 24, 1910,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Acetylene machine, pipe frame for, L. E. Lake ... 959,[illegible]
Adding and subtracting machine, O. F. Kettering ... [illegible]
Adhesive compound or [illegible] ... [illegible]
Advertising [illegible] ... [illegible]
Aerial [illegible] ... [illegible]
Air [illegible] ... [illegible]
Air brake testing apparatus, F. H. Dukesmith ... 959,193, 959,194
Air brake testing system, F. H. Dukesmith ... 959,[illegible]
Air heater, W. N. Le Page ... 959,[illegible]
Airships, device for feeding ballonnets on, M. Kapferer ... 958,[illegible]
Alloys, making copper, G. Boericke ... 959,[illegible]
Annunciator drop, C. Auth ... 959,192, 959,194
Asparagus and kindred plants, treating, E. C. Kline ... 958,[illegible]
Automatic lubricator, J. W. Shafer ... 959,[illegible]
Automobile engine starting device, A. M. Walstrom ... 958,[illegible]
Automobile steering wheel, R. R. Bowers ... 959,[illegible]
Automobile wind shield, sectional, A. L. Woodward ... 959,188
Axle box dust guard car, Briggs & Millett ... 958,933
Axles, stay and other bolts, etc., rod for, F. M. Patterson ... 959,159
Baling press, F. W. Williams ... 958,910
Baling press feeding device, C. J. Johnson ... 959,144
Ball joint, flexible, O'Neill & Neubeck ... 959,278
Bank note gatter, H. K. Hoke ... 959,342
Barrel carrying device, S. C. Jensen ... 958,923
Barrow dumping, L. M. Schoonmaker ... 959,265
Bearing, combination roller, C. S. Lockwood ... 958,903
Bearing roller, W. W. Dennis ... 958,907
Beater and mixer, W. H. Ashby ... 959,430
Bed, frameless spring, T. A. B. Putnam ... 959,164
Bed pan, elastic, F. M. Otis ... 959,379
Bed, screen, O. O. Richardson ... 959,[illegible]
Bedclothing rest, M. R. L. Bergen ... 958,718
Bedstead spindles, means for securing, J. C. Wilson ... 959,098
Belt pin or buckle, L. Hauser ... 959,340
Binder, temporary, C. D. Trussell ... 959,182
Binder, temporary, C. D. & H. A. Trussell ... 959,183
Blind holder, window, O. Thomasen ... 959,403
Block molding machine, J. W. Bragstad ... 959,050
Blower, positive pressure, F. P. Boland ... 959,049
Boat fender brake, J. Boydell ... 959,299
Boiler attachment, locomotive or other, C. F. Harris ... 959,134
Boiler cleaning attachment, water tube, E. Stephenson ... 958,942
Boiler flue, detachable, J. F. Drake ... 958,910
Boilers, automatic jack for engine, C. Kent ... 958,928
Book cover, metallic, Andrews & Turner ... 959,284
Book holder, W. O. Traher ... 959,405
Book holder sales, N. F. Garbo ... 958,730
Book smashing machine, S. K. White ... 958,787
Boot or shoe attachment, O. Waldstein ... 958,984
Boring machine, G. H. Smith ... 959,183
Bottle capping machine, milk, D. S. Yard ... 959,038
Bottle cap remover and stopper, combined, A. R. Hoeft ... 959,220
Bottle, non refillable, W. O. Wilson ... 959,186
Bottle, non-refillable, C. Councell ... 959,207
Box blank and using the same, J. F. Adams ... 959,098
Box fastener, J. P. Frits ... 958,916
Box making machine, G. D. Parker ... 959,158
Brace clamp, J. D. Maddox ... 959,147
Bread mixer, W. A. Rabbitt ... 959,101
Breakers, spreaders, etc., automatic regulating device for, W. H. L. Mellis ... 959,148
Brick making apparatus, W. Hanley ... 959,068
Brick, manufacturing, J. C. Dunton ... 958,907
Brick molding machine, T. Young ... 958,808
Brick setting frame, R. C. Penfield ... 958,973
Briquet machine mixing apparatus for, G. Komarek ... 959,062
Briquets, manufacturing, T. G. A. Wilson ... 958,930
Brooder, C. K. Adair ... 959,007
Broom corn and the like, machine for bundling or compressing, J. F. Foley ... 958,868
Broom holder, J. T. Holte ... 959,139
Brush, dental, J. H. Abbott ... 959,191, 959,416
Brush holder, P. T. Flach ... 959,211
Buckle, W. A. Holden ... 959,138
Bundle or package tie, F. S. Chappell ... 959,310
Bush puller, J. G. O'Donnell ... 959,377
Butter or cheese receptacle, N. D. Burton ... 958,991
Button cutting and drilling machine, R. McCoy ... 959,131
Cable hanger, F. D. Ogden ... 959,004
Cable splicer, J. Urbans ... 959,407
Can. See Oil can.
Can caps, means for applying solder rings to, W. J. Phelps ... 959,163
Can forming apparatus, C. W. Graham ... 958,741
Cans or the like, closing device for, H. Hintermann ... 959,013
Candy cutting machine, J. H. Bennett ... 958,717
Cane, apparatus for treating sugar, A. & S. Wynberg ... 958,790
Car buffer, mine, V. E. Lane ... 959,232
Car coupling, D. S. Montgomery ... 958,884
Car door, F. Horn ... 958,873
Car fender, A. H. Carter ... 959,309
Car lines, apparatus for tabulating the passenger traffic on, J. T. Crabbs ... 959,313
Car, mining, J. Blair ... 959,294
Car roof, J. Marold ... 959,366
Car wheel, E. A. Johnson ... 958,926
Car wheel press, G. T. Heiss ... 959,071
Carbureter, J. W. Snedeker ... 958,807
Carbureter, W. Ottaway ... 959,098
Carbureting apparatus, G. Johnson ... 959,350
Cards, device for reflecting the concealed side of, W. T. Peckham ... 958,763
Cards, head for punching five and six frame brussels, W. K. Caldwell ... 959,200
Carpet fastener, H. Wainstock ... 959,277
Caster, G. W. Bent ... 959,106
Cautery, electric, W. Meyer ... 958,733
Centering apparatus, J. T. Rice ... 959,167
Centrifugal separators, hollow shaft for, C. H. Shaw ... 959,030
Chain and wheel therefor, drive, W. J. Belcher ... 959,046
Chain drive, W. J. Belcher ... 959,047
Chair fan attachment, rocking, P. Pezanne ... 959,384
Chicken hovel, J. S. Pelrounet ... 959,181
Chimney top, A. Zwingli ... 959,415
Chlorid solutions, regenerating stannic, J. Weber ... 958,996
Chuck, G. J. Thomas ... 958,980
Churn, A. Massie ... 959,367
Cigar band, G. Labatre ... 959,357
Cigar carrying and displaying receptacle, A. G. Kaufmann ... 959,078
Cigar clipper attachment for pencils, J. O. Thorne ... 959,272
Cigar maker's box and rolling board, J. Kiett, III ... 959,085
Circuit closer, H. O. Thomson ... 959,435
Clevis, R. H. Hammock ... 959,420
Clock, alarm, G. Kern ... 958,830
Closing disk, W. L. Wright ... 959,095
Clothes line support, W. L. Anderson ... 959,419
Coal and rock drilling machine, C. Beals ... 959,079
Coal coking, S. B. Sheldon ... 959,090
Coaster brake, T. Fulkos ... 958,796
Coat, P. Shotland ... 958,977
Cock, basin, J. F. Kelly ... 958,927
Cock, safety gas, H. Van Wickle ... 959,090
Coiling mechanism, F. H. Richards ... 958,767
Coke ovens, folding coke and coal handling machine for, J. R. A. Moore ... 959,346
Color stamping, composition of matter adapted for use in the art of, S. Weinberg ... 959,185
Colors and making same, nitro-ortho-oxy-azo, K. Mied ... 958,912
Combination lock, O. M. Larkin ... 959,294
Composition of matter and making same, W. A. Phillips ... 959,088
Concrete pile, metal reinforced, R. Mohns ... 958,967
Concrete, support for, J. P. Hallahan ... 959,317
Concrete wall construction, L. Lapennonerie ... 959,360
Controller, F. D. Hallock ... 958,808
Controlling mechanism, fluid operated, J. W. Anderson ... 959,417
Cooler, O. A. Kersey ... 958,981
Copying device, press, H. A. Benner ... 959,383
Corset, J. E. Wyant ... 959,189
Cork tapering machine, J. T. McCready ... 958,754
Corn-cleaner and separator, shelled, D. R. Raworth ... 959,[illegible]
Cot holder, M. E. Rodrigues ... 958,[illegible]
Cotton chopper, R. P. Simmons ... 959,051
Coupling. See Car coupling.
Crate, collapsible, L. M. Leibowitz ... 958,749
Crating apparatus, chicken, J. De Young ... 959,121
Cross arm brace, J. D. Love ... 959,[illegible]
Cross and [illegible], H. D. Pennington ... 959,[illegible]
Crushing or pulverizing machine, J. L. [illegible] ... 958,[illegible]

A [illegible] ROTARY ENGINE.

(Concluded from page 466.)

the Parsons and Curtis types, the rotary engine serving the purpose of utilizing steam of the higher pressures under a high degree of superheat with the greatest possible mechanical efficiency and exhausting the steam at a pressure which can be readily used within the turbine, offers possibilities in economy far beyond the scope of any apparatus heretofore presented." He estimates that such a combination would show a water rate of 10.8 pounds per B. H. P.

He assumes the case of a modern battleship, with 36,000 horse-power developed on three screws, the outer screws driven by turbines of 15,000 horse-power, and 140 pounds initial pressure, the center screw being driven by a Herrick rotary engine of 280 pounds absolute pressure and a superheat of from 100 to 200 degrees. Assuming a water rate of 13 pounds for the turbines, Mr. Lovekin arrives at his ultimate water rate of 10.8 pounds for the combination as follows:

The revolutions of the turbines will be 275 per minute.

The revolutions of the rotary engine will be 160 per minute

The effective stroke of the rotary engine will be 17 feet.

The clearance will be 12 per cent.

The stroke, plus the clearance, will be equal to 19 feet.

The distance swept by the piston per hour, allowing for clearance, will be $19 \times 160 \times 60 = 182{,}400$ feet.

The total cubic feet of steam used will be $390{,}000 \times 3.2 = 1{,}248{,}000$

The area of the piston will be

$$\frac{1{,}248{,}000}{182{,}400} = 6.85 \text{ square feet.}$$

Assume pistons 16 inches high,

$$\frac{6.85 \times 144}{16 \times 3} = 20\tfrac{1}{2} \text{ inches,}$$

width of each piston. (3 in all.)

The horse-power developed by the rotary engine is as follows

2 expansions = 0.8465

280 × 0.8465 = 237 pounds.
140 pounds back pressure.
97 pounds.
0.80 ratio of actual mean to theoretical pressure.
77.60 (Approximate.)

$$\frac{78 \times 17 \times 6.85 \times 144 \times 160}{33{,}000} = 6{,}280 \text{ H. P.}$$

for rotary engine.

Assuming 6,000 B. H. P., with a propeller efficiency of 60 per cent.

The turbines will give out 30,000 B. H. P at 50 per cent

The rotary will give out 6,000 B. H. P at 60 per cent.

Total . . . . . . . . 36,000 B. H. P.

$$\frac{390{,}000}{36{,}000} = 10.8 \text{ pounds of water per B. H. P.}$$

RADIUM BATHS.

(Continued from page 461.)

ried into practice on a large scale by the Administration of the Municipal Salines of Kreuznach, Germany, where drinking and bathing water, artificially treated by the very radioactive substances contained in the springs, is manufactured and sold.

Though details of the process used in this connection are as yet kept secret, we are enabled by the courtesy of the administration mentioned, to place before our readers a general account of the methods by which brine is prepared and treated for radioactive substances, which in their turn are used to energize ordinary drinking water or to increase the efficiency of any therapeutic product.

The Kreuznach brine, which contains besides other elements iodine and bromine, yields, after boiling [illegible]

(*Continued from page 468.*)

the mother liquor this process is very complicated and expensive

The brine is vaporized in graduating works, the output of which depends on the season, the direction and intensity of winds, as well as on the temperature and moisture of the air. Each of these graduating works (the total length of each is approximately 2.5 kilometers) is divided into seven compartments of decreasing lengths traversed consecutively by the brine, and the salt content increasing as each compartment is traversed. After leaving the last compartment the weak solution is from eight to twelve times more concentrated. The hrambic walls of the compartments are exposed to the wind. Hence operation of the plant is difficult in variable winds. On the other hand, the surrounding air which is strongly ozonized and charged with atomized brine, not only makes the graduating works a very cool and pleasant place to stay in on hot days, but affords a welcome opportunity for utilizing the curative effects of the refreshing salt air.

The pumps of the graduating works are operated by a number of water wheels fed from the river Nahe through a system of canals. From the graduating works the brine is pumped through conduits to the reservoirs of the evaporating house, in order there to be boiled.

Both the evaporating house and graduating works date from the middle of the eighteenth century when the Salines were erected, the ancestors of most of the workmen employed therein having spent their lives in the works.

The primitive boiling process carried out in open salt pans has recently given way to a modern multiple vaporiser with improved devices for recovering the mother liquor and the salt. It consists of a steam boiler and a number of vaporizers, an air pump, etc.

As the boiling of the brine and mother liquor is carried out *in vacuo* at low temperature, the decomposition of valuable chemical compounds is entirely prevented, thus increasing the curative effects of the products.

When the brine has been boiled down to such concentration as to contain in a hundred kilogrammes twenty-two kilogrammes of common salt, a supersaturated solution is obtained from which the salt crystallizes. As the concentration of the brine increases, then increasing amounts of salts are separated, which impart to the salts an acid taste. These salts are used for various therapeutic purposes, while the brine left after the separation of the common salt forms the mother liquor used for other therapeutic purposes and of which about 250 000 liters are produced per annum. For shipping great distances, the mother liquor is further concentrated until it crystallizes in lumps.

Experiments commenced in 1904 have shown that the Kreuznach water contains not only plentiful amounts of gaseous radioactive emanation but carries along from the interior of the earth radioactive substances. Part of these substances, as the water during the graduating process comes into contact with the air, will separate along with iron oxide, calcium and barium carbonate, while another part remaining in solution forms in the brine a permanent source of emanation. Experiments made by Elster and Geitel, as well as by Dr. K. Aschoff, have shown that the residues contain not only considerable traces of radium, but radiothorium and actinium as well. The mother liquor derived from the Kreuznach brine as well as from the bathing salt was likewise found to be strongly radioactive. Further experiments demonstrated the possibility of isolating traces of radium from the residues of concentrating the radium salts. As the springs of Kreuznach yield every year radioactive residues by the hundredweight, it was deemed advisable to attempt the production of radium salts on a large scale. Mr.

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

START AN EASY and lucrative business. We teach you how to establish a successful collection business and refer business to you. No capital required. Little competition. Rare opportunities. Write for Free Pointers today. Am. Collection Service, 18 State St., Detroit, Mich.

Inquiry No. 8018. For manufacturers of Wydt's Electro Catalytic Sparking Plug.

100 PER CENT profit selling the Lindsay soft inverted mantles; fit any inverted gasoline light. Steady customers in every town. Fine side line for salesmen. Vest pocket samples and prices on request. Lindsay Light Co., Dept. 8, Chicago.

Inquiry No. 8087. Wanted the manufacturers of the Van Winkle [illegible] & Sons and the Weber power meters.

PROMOTER WANTED to interest capital in a railroad grading machine. The machine has been built, tested and proven a success. Will pay liberal commission. Promoter, Box 773, New York.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

## FOR SALE

FOR SALE.—Interest or control in manufacturing business. Exceptional opportunity for manager or instrument maker. Contra, Box 773, N. Y.

Inquiry No. 9019. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

AUTOMATIC LEMONADE MACHINES for sale and patents. Good chance. Address A. E. Griffith, 318 West 11th Street, New York City.

Inquiry No. 9021. Wanted to buy silk machines from the reeling, twisting, doubling to the final process of making it into clothes.

FOR [illegible] I WILL SELL MY SECRET of solution that will hold the moist in dry battery cell. My secret and Hot Springs, Ark., waters will make the best dry battery in the world. For further particulars, address Oscar Nelson, 10 St. Marks Avenue, Brooklyn, N. Y.

Inquiry No. 9029. Wanted catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## WANTED

WANTED address of dealers, manufacturers, or inventors of proved dry placer mining machine for extracting even small percentages of gold from dust or dry sand. Address L. C. Scherer, Ft. Bayard, New Mexico.

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9066. Wanted to buy machinery to manufacture seed corn racks.

## SALE AND EXCHANGE

FOR SALE. Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $42.50. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9075. Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9077. Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

## MISCELLANEOUS.

WE are about to complete a large contract for Taxi meters and are therefore in a position to take up experimental work, manufacture of fine instruments, parts for the same, dies, jigs, etc. Precision Tool & Instrument Co., 8-10 Canal Place, New York City.

Inquiry No. 9078. Wanted the address of manufacturers of sewer pipe made of fiber and asphaltum suitable for laboratory use.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste making machinery.

Inquiry No. 9083. Wanted the address of firms manufacturing small beer brewing plants from 15 to 100 gallons a day.

Inquiry No. 9091. Wanted the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9094.—Wanted address of The Thomas Arithometer Company, also Burkhart Arithometer Company.

Inquiry No. 9096.—Wanted the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted name and address of the manufacturers of the ozonizer.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9101. Wanted addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9107.—Wanted addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109. Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9113. Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114.—Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9116.—Wanted a machine for making [illegible] similar to Wm. Mitchell's G & J nibs and Waverly nibs.

Inquiry No. 9117.—Wanted names and addresses of the manufacturers of [illegible].

Inquiry No. 9118. Wanted a muffler for a gasoline engine built upon the principle of the Maxim silencer recently brought out for use on rifles.

Inquiry No. 9119. Wanted name and address of the manufacturer of Martin bullet proof cloth.

Inquiry No. 9120.—Wanted the address of the Idea Fuel Feeder Co.

Inquiry No. 9121.—Wanted manufacturers of cut stencils for fancy work, sofa pillows, etc., and oil colors and brushes for same.

Inquiry No. 9124. Wanted name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9127.—Wanted address of L. Dermigny, manufacturer of a family ice machine for $[illegible].

Inquiry No. 9128. Wanted manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots used in making oil of sassafras.

Inquiry No. 9134.—Wanted a small hydraulic motor capable of giving about one horse power with a water power of 55 lbs. per square inch.

Inquiry No. 9135.—Wanted name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted a device that will braid leather strips for horse whips.

Inquiry No. 9138.—Wanted the address of manufacturers of machines capable of forming a number (12 or more) of pieces of paste about 38 mm. x 8 mm. x 6 mm. made of lead oxide and sulphuric acid and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139.—Wanted the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted manufacturers of disc records for gramaphones that use a sapphire point instead of a steel needle.

Inquiry No. 9142.—Wanted name and address of the manufacturers of an air seat ram.

Inquiry No. 9144.—Wanted manufacturers of machinery for making soda water tubes commonly known as straws.

Inquiry No. 9145. Wanted to buy machinery to load blasting caps or detonators.

Inquiry No. 9149. Wanted manufacturers of machinery for roasting coffee for small and large industries.

Inquiry No. 9150.—Wanted manufacturers of machinery for the manufacture of French heels for ladies' shoes.

Inquiry No. 9151.—Wanted the address of the Graham Safety Lamp Filler and Ventilator.

Inquiry No. 9152.—Wanted name and address of manufacturers of a knotless clothes line.

Inquiry No. 9151. Wanted name and manufacturers of a newspaper vending machine.

Inquiry No. 9153. Wanted the address of manufacturers of an electric milking machine.

Inquiry No. 9156.—Wanted the name and address of manufacturers of a rust proof oil known as Caseboso Oil.

Inquiry No. 9157.—Wanted manufacturers of peanut shelling and cleaning machinery.

Inquiry No. 9158.—Wanted manufacturers of a material in sheets to take the place of galvanized iron for novelty work.

Inquiry No. 9159.—Wanted manufacturers of any successful substitute for hard rubber.

Inquiry No. 9161.—Wanted, a machine that will grind oranges, pulp and skin into a smooth liquid or cream.

Inquiry No. 9162.—Wanted, addresses of shirt makers in Manhattan who will make a few shirts of special design.

Inquiry No. 9163.—Wanted, manufacturers of a cradle worked by clock work.

---

Neumann, Director of the Kreuznach Salines undertook experiments according to a method worked out by Dr. Aschoff. One of the wings of the boiling house was converted into a radium factory, which has been operated for over a year. The entire annual production of active residues is now worked into radium salts, an end which has made possible an extensive therapeutical use of radium compounds, both as a white insoluble powder of high radioactivity for compresses, ointments, etc., or directly in a dried condition, and—on a far larger scale—in the shape of gaseous emanation transmitted to water.

An apparatus perfected by Mr. Neumann renders it possible to determine the amount of emanation imparted to a given quantity of water.

Mr. Neumann has recently worked out an improved charging method which is especially suited for imparting to any liquids a very intense activity (2 000 to 50 000 Mache units). However no details as to this method have as yet been made known.

Satisfactory results have been obtained by treating, by means of charged drinking or bathing water, chronic rheumatism of the joints, and gout, while a number of other complaints are favorably acted upon.

An interesting fact ascertained by those physicians who have tried the radium-water treatment, is that many patients at the beginning of the cure will show a striking reaction, consisting of a recrudescence of some symptoms of the malady, and in some cases in some trouble in the general condition (insomnia, loss of appetite, etc.). In some cases this reaction manifests itself as a slight feeling of intoxication during the bath and some minutes afterward, while other patients feel especially refreshed and invigorated. This reaction, which strikingly resembles the reaction produced by many natural bathing and drinking waters, is a presage of success.

Though this radium-water cure, is yet of too recent date to allow definite conclusions to be drawn, it doubtless constitutes a valuable addition to the present methods of modern medicine.

## ALEXANDER GRAHAM BELL.

(Continued from page 462.)

the free end of one of his steel reeds to the center of a membrane capable, like the ear drum of taking up any kind of vibration. The fixed end of the reed was not to be clamped but was to be hinged loosely to the polarising magnet, so that it would no longer have any definite rate of vibration but would follow all the vibrations of the membrane. A similar instrument was to be used as a receiver. But the apparatus was not constructed at that time because Bell doubted whether the currents generated by the action of the voice alone would suffice for practical telephony. Furthermore, he was induced by his associates to devote his attention to multiple telegraphy.

One day in tuning and testing the clamped reeds of his transmitters and receivers he found that the receiving reed vibrated and sounded when the transmitting reed of the same pitch was plucked although the battery was not in circuit. This discovery convinced him that the membrane speaking telephone devised a year earlier could be made to work.

The long and patient researches that followed cannot be here detailed. Membranes with attached patches of iron and steel of various dimensions were tried and the apparatus was varied in many other ways. Then it was discovered that a thin sheet of iron could be used as the membrane. Thus were developed, successively, the apparatus patented in 1876, the telephones that created so profound a sensation at the Centennial Exhibition in the same year, the instruments patented in 1877 and the familiar hand telephone which with some modifications, is still universally employed as a telephone receiver.

From the beginning Bell had aimed at the production of an undulatory current capable of representing all the component harmonic vibrations of vocal sounds. This fact sharply distinguishes his invention from the old Reis telephone which, employing an intermittent current produced by alternately making and breaking the circuit, reproduced only the pitch of a sound, but not its quality or *timbre* and was consequently unable to transmit vocal sounds and articulate speech.

It is safe to say that no patents for any invention have been subjected to such long and bitter litigation as the Bell telephone patents. During one of the many suits which involved the validity of the patent Mr. Bell was on the stand for fifty-two days during which time he recited the history of his invention with a clearness and conciseness that still characterize both his writings and his speeches. As we see it to-day, the telephone is practically the same in principle and construction as when it left its inventor's hands, so far as the receiver is concerned. Few inventions have changed so little. To be sure, the appearance of the apparatus has been greatly modified. The multiple switchboard and the common battery system have been introduced, and the very difficult art of telephone engineering has been developed. But for all that, the telephone still remains the same in principle.

Professor Bell makes no claim to business ability. He even states that had it not been for his father-in-law, Mr. Hubbard

(Concluded on page 471.)

(Continued from page 47[illegible].)

[illegible] first president of the first telephone company, it is doubtful if the telephone industry would have been so rapidly developed. Fortunately, the original owners and promoters of the telephone were, above all, business men, actuated by the sole idea of developing the business along broad lines. Whatever reward they expected or received was the legitimate reward following the legitimate development of a substantial and beneficial business. To develop that business it was first necessary to develop an art. There was nothing like that art in existence at the time. Indeed, the whole art of the practical application of electricity was new

The telephone is not the only art with which Professor Bell's name is linked In wireless signaling, too, he made some early experiments which, had they been extended, might eventually have led him into the field of wireless telegraphy and telephony During experiments which he made on the Potomac River in 1878 and 1879, he succeeded in signaling for over a mile He informed the writer of this article that an account of his work on the Potomac River which he gave to Preece in England, may possibly have influenced Preece in his own work His attention was first called to the subject in 1877, when he was experimenting on ground connections He used pokers as terminals. When he thrust a poker into the ground and put the telephone to his ear he heard a clock ticking It was the Cambridge Observatory clock, which he easily recognized because it missed a tick now and then as it regulated the time in Boston Cambridge was nowhere near Mr Hubbard's country seat, where the experiments were conducted

Aerial locomotion is another art with which Professor Bell has become identified His interest in the subject was aroused when, in 1880, he began to make kite-flying experiments, largely for the sake of his health He started with a Hargrave box kite and eventually developed the tetrahedral principle, which is now well known among aeronauts. During the course of his experiments he found that he needed the services of civil and mechanical engineers Accordingly, a little association was started under the name "Aerial Experiment Association," which included among its members the late Lieut. Selfridge, Glenn Curtiss, Baldwin, and McCurdy, all of them now well known. Baldwin and McCurdy acted as engineers, Curtiss was the motor authority. The association was Mrs Bell's idea, and was founded to carry on Mr Bell's own work. She sold the only piece of property which was hers in her own right, and which had not been given to her by Mr Bell, in order to finance the association. Although these engineers were all originally engaged to help Mr Bell in his tetrahedral experiments, the members of the association ended by helping one another Selfridge was the first man who profited by the association's assistance. Believing that it was best to follow in the footsteps of others, and then to improve on their work, he started with gliders, and finally built the "Red Wing," which flew successfully Next came Baldwin's chance He embodied his ideas in the "White Wing," in which wing tips were introduced, controlling devices which are now the subject of so much controversy Then came Curtiss's "June Bug," which won the Scientific American Trophy McCurdy followed with the "Silver Dart." Baldwin and Bell worked at the tetrahedral principle in Nova Scotia, experiments which are not yet concluded. Curtiss remained at Hammondsport, New York, and Selfridge was recalled to Washington by the War Department. The association was so scattered that it was necessary to adopt some means of communication. Hence, the weekly bulletins were started under the title "Bulletin of the Aerial Experiment Association," which had a combined circulation of seven, and which served the purpose of keeping the members in touch with one another

**HEIGHT OF THE ANTARCTIC CONTINENT.**

*(Concluded from page 464.)*

concludes that, if the continent covers an area of 5,200,000 square miles as Bruce and Kreummel assume, its mean elevation above sea level is about 6 600 feet with a probable error of ± 660 feet.

If this estimate is approximately correct, as the results of the recent explorations appear to indicate, the Antarctic continent is by far the highest mass of ~~land on the globe~~ By the addition of this huge polar cap the mean elevation of the entire land surface of the earth is increased from 2,312 feet to 2,706 feet.

The process by which Meinardus reached these conclusions may be sketched as follows It was already known that the mean height of the barometer over the northern hemisphere is 0 8 millimeter higher in January than in July, but that the corresponding barometric height for the zone extending from the equator to 50 degrees south latitude is 2 1 millimeters lower in January than in July Hence, as the entire mass of the atmosphere and consequently the average atmospheric pressure over the whole surface of the globe remains constant, the mean barometric height for the zone south of 50 degrees south latitude, which is equal in area to about one-fourth of the southern hemisphere, must be about 3 6 millimeters greater in January than in July

The observations made by recent explorers, however, led Meinardus to the conclusion that the mean atmospheric pressure over the zone lying between 50 degrees south latitude and the Antarctic circle is not greater, but is 0 73 millimeter less in January than in July This result increases the January deficit of pressure and restricts the area in which it can be made up to the Antarctic zone, in which, consequently the mean atmospheric pressure must be 11 millimeters higher in January than in July Within the Antarctic circle the only observations available for this discussion are those of the ships Discovery Belgica and Southern Cross,' which together comprise the records of four entire years In three of these years the atmospheric pressure was lower in January than in July Thus the area in which compensation for the deficit can be sought is still further restricted, apparently to the Antarctic continent

Meinardus finds the explanation of this puzzling state of affairs in the great height of the Antarctic continent The atmospheric pressure diminishes as the elevation of the point of observation increases, and the difference is greater at low than at high temperatures Hence, in a region where the atmospheric pressure is constant throughout the year at the sea level, it is appreciably higher in summer than in winter at an elevation of several thousand feet. For a given elevation this difference increases with the difference between the summer and the winter temperature Meinardus and Hann have computed that the mean atmospheric temperature of the Antarctic continent is +26 6 deg F in January (Antarctic midsummer) and −14 8 deg F in July (Antarctic midwinter) In these conditions it can be calculated that the mean excess of January over July pressure (11 millimeters) required for the entire Antarctic zone would be furnished by a mean elevation of that zone of about 4 400 feet on the assumption of a constant atmospheric pressure at the sea level But the coasts of the Antarctic continent have been explored sufficiently to make it reasonably certain that that continent occupies very approximately, two-thirds of the entire area of the Antarctic zone Hence, on the assumption of a constant atmospheric pressure over the remaining third which is covered by water, Meinardus arrives at the conclusion that the average height of the Antarctic continent is about 6,600 feet

NEW YORK, SATURDAY, JUNE 11th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

### THE NEW ERA OF AERONAUTICS IN AMERICA

IT is a curious anomaly that, although America is the birthplace of the practical flying machine—a distinction which is universally admitted and stands in little danger of future disputation—the further development of the art of flying, as first demonstrated by the Wright brothers, has hitherto been confined mainly to European countries. To us, it has always seemed probable that our apathy was more apparent than real, and that when sufficient stimulus was offered, the art of aviation was sure to come into its own, and its development be prosecuted with a zeal that was worthy of the energy and liberality of the country in which the first practical flying machine had its birth.

Evidently the needed spur has been afforded by the phenomenal achievement of Glenn H. Curtiss in making his recent flight from Albany to New York at the unprecedented speed of over fifty miles an hour—a feat which vindicated both the far-sightedness and the liberality of the New York World in offering a prize of $10,000 for such a flight in connection with the recent Hudson-Fulton festival.

Apart from the fact that so great a distance was covered at so high a speed, there are other considerations which largely account for the powerful hold which this flight has taken upon the public imagination, such, for instance, as the altogether untried nature of the course, the almost complete absence of suitable landing places, and the absolute composure with which, when an emergency landing had to be made, the aviator circled in his path, swooped down, bird-like, upon a small open clearing above the rocky and hill-covered cliffs, landed, started again on the final leg of his course above the crowded shipping of the North River, and finally came to rest on Governor's Island at the very doors of the house which was built for him during the Hudson-Fulton aeronautical contests. Here was a man who at the very first trial and over a course which, because of the encompassing mountains and ravines and the resulting air currents, was believed to be exceptionally difficult, accomplished with evident composure and at times with a suggestion of complete *sang froid* a feat of flying which only six months before, was regarded as a dream of the enthusiast.

When the news of his accomplishment was flashed throughout the country, its effect was instantaneous and positively electric. The last doubt as to the practicability of long-distance cross-country flying vanished, and the evidence of the awakening was shown in the almost immediate offer of over $100,000 in prizes for flights of a similar character, to be held during the present season to various parts of the United States. First came the simultaneous and munificent offers of $25,000 by the New York Times and the Chicago Evening Post for a Chicago-New York flight of about 960 miles, and of the New York World and the St. Louis Post-Dispatch of $30,000 for a St. Louis-New York race over a 1,000-mile course. Then the Washington D. C. Chamber of Commerce and the Aero Club of Washington offered $20,000 for a 225-mile race from Washington to New York, and as we go to press a $10,000 prize is being promoted in St. Louis for a flight from that city, over a distance of about 250 miles, to Kansas City, and $5,000 is offered for a flight over a 250-mile course from Indianapolis to Chicago.

Such are the attractive prizes that have been made available, within a week of Curtiss's flight, to promote long-distance feats of the same character. At the same time, through the liberality of Mr. Edwin Gould, as noted elsewhere in this journal, attention is being directed to the mechanical improvement of the aeroplane itself, with a view to enlarging its ability to remain continuously in the air and extend the duration of its single flights. The offer of the large sum of $15,000 for the best successful aeroplane provided with two motors, one to be held in reserve for emergency, is certain to prove a great stimulus to inventors and constructors, and should result in the production of some very interesting combinations of motive power.

The above *résumé* of the happenings of the past week surely justifies the statement that, when the history of the art of flying in America comes to be written, this period will stand out as second only in importance to those ever-memorable days, when the Wright brothers were making their flights above the sand hills of North Carolina in the first practical man-carrying and controllable aeroplane propelled by its own motor.

### THE PERIL OF THE SUBMARINE.

JUDGED by the number of tragic disasters which has overtaken the submarine during the past few years, this greatly dreaded instrument of war might seem to be as great a menace to friend as to foe. In the absence of accurate information as to how many lives were accounted for by the submarine during the Russo-Japanese war, it is a question whether in the last ten years the submarine has not caused the death of a greater number of its own crews than it has of the enemy, and we hazard the statement that considerably over half a hundred lives have been sacrificed during the past ten years in the ordinary peace maneuvers of submarine vessels. The long roll of disaster is headed, in point of loss of life, by the sinking of the French vessel "Pluviose" on May 26th last, off Calais, when 28 officers and men lost their lives. The most fatal, as it is the most frequent, cause of accident is collision. We all remember the running down of a British submarine off Spithead by an outward-bound Orient liner which came up from behind unnoticed, and apparently passed entirely over the submarine. Within the year a similar accident happened at the entrance to the English Channel, when a large ship ran through a fleet of submarines at night time, sinking one of the boats. To the same cause was due this recent French disaster, the "Pluviose" being struck by the paddle-wheel of a Calais-Dover passenger steamer as the latter was leaving Calais harbor.

At the same time, although we deplore the terrible loss of life which has occurred, we must not permit these disasters to shake our faith in the utility of the submarine, for the accidents have been chargeable to inefficient handling, or, shall we say to lack of sufficiently wide experience, rather than to any inherent mechanical defects in the design or construction of the submarine itself. In recent years, outside of those due to collision, the losses have been chargeable, not to theoretical or mechanical defects in the boats themselves, but to carelessness or inexperience in their manipulation. Testimony to this effect was afforded by the diary (an amazing document) which the commander of the Japanese submarine, that was recently sunk, continued to write up to the very hour of his death, in which, with characteristic Japanese nobility, he took the blame for the loss of the vessel directly upon himself. Mechanically speaking, the highly-developed submarines of to-day, as exemplified in the latest types built for our own navy, are thoroughly reliable. The writer speaks from experience, having spent some four hours and traveled some twenty miles under the sea last summer off the point of Cape Cod, in the recently completed "Stingray." The vessel descended, ran on an even keel, rose to the surface and was steered, with absolute precision; the air within the submarine was perfectly wholesome and free from odor, and the composure of the officers and crew betokened a perfect confidence in the stability of the vessel.

The disaster to the "Pluviose" proclaims the necessity for that eternal vigilance which is the pledge of safety in travel not merely beneath the sea, but in the air and on the dry land. The charge can be no longer made against the submarine that it is "blind." In the perfected periscope, the vessel is provided with an eye whose vision is as clear as that of the binoculars of a commanding officer on the bridge of a warship. Furthermore there has been produced and is now obtainable a periscope which commands a view of the complete horizon during such time as the submarine is within, say, ten or fifteen feet of the surface, and with such an instrument, given clear weather and a careful lookout, the danger of being run over by a ship coming up from behind should be completely eliminated. The accident to the "Pluviose" seems, however, to have been due to the submarine rising to the surface just ahead of, and in the path of, the Calais steamer. Here is a very real and not easily prevented danger. Although the commanding officer may take a careful survey of adjacent waters and note the position of other craft before he dives, such is the speed of modern vessels that a ship may easily have passed into close proximity by the time the submarine rises again to the surface, even though the period of submersion be limited. Collision on rising to the surface is a form of accident which for the present, at least, must be regarded as not entirely preventable.

### "MECHANIPULATE."

IF the proper role for language to play in the round of our daily life is that not of master, but of servant of our necessities, we should surely be at liberty to add new words to our vocabularies whenever necessity calls for them. Let it be remembered, however, that the addition of the new word and the modification or elimination of the old should be done always in a spirit of profound conservatism, and only under the spur of a well-recognized necessity.

It is agreeably to this spirit that we indorse the use of the word "mechanipulate" to designate the handling of a piece of work by a machine. At the present time, all the many elaborate and ingenious operations which are performed by mechanical hands and fingers frequently with a close approximation to the delicacy and dexterity of the movements of the human hand, have to be designated by the word "manipulate"—which is distinctly a misnomer. If the work in question could be manipulated with the same facility, dispatch, and economy with which it is *mechanipulated*, the mechanical operations would never have been introduced. The credit for the suggestion of this serviceable word is due to Mr. Henry A. W. Wood, and as far as we know, its first use is to be found in his article on "Modern Stereotypy," in the issue of the SCIENTIFIC AMERICAN SUPPLEMENT of May 14th, in which, speaking of a plate that has been cast he says: "It is left face up . . . in position to be most easily mechanipulated, . . . the mechanism used for the purpose acting with a gentle, uniform motion to position the matrix with accuracy," etc. Then, in a foot note the writer says: "In my experience, I have frequently felt the need of a word which should express the 'handling' of its work by a machine, as the word 'manipulate' expresses the handling of the work of a man by his hands. To fill the gap I have made bold to coin and use the word 'mechanipulate,' which is here employed." In bringing the suggested word to the attention of the public, we invite a discussion of its merits in the correspondence columns of the SCIENTIFIC AMERICAN.

### THE COLDEST REGION OF THE ATMOSPHERE

THE decrease in the temperature of the air with increasing altitude—exemplified in the fact that the top of a mountain is colder than its base—is a matter of common knowledge. It is a fact that occasional inversions of this distribution of temperature may occur—as when fruit trees in a valley bottom are nipped by a frost that does not touch the hilltops; but it remains true in general, that the temperature of the air decreases upward and that the air at great altitudes is extremely cold as compared with that at the surface of the earth.

Until Teisserenc de Bort announced his discovery of the isothermal layer, eight years ago, it was not suspected that this decrease of temperature did not extend upward to the limits of the atmosphere. Now, however, we know that at a certain altitude, averaging in middle latitudes, about 11,000 meters (7 miles), the fall in temperature with increasing altitude ceases rather abruptly, usually giving place to a *rise* of temperature for a certain distance upward, above which the temperature remains approximately constant as far as the highest ascents of sounding balloons have carried thermometric apparatus.

Hence, above any given spot on the earth's surface the air is coldest just below the region of the upper inversion, which marks the beginning of the great isothermal layer (or, as it is now called by its discoverer, the *stratosphere*).

The altitude of the isothermal layer varies with the barometric pressure at the earth's surface, with the season, and especially with the latitude. It is somewhat less over the poles than over middle latitudes and very much greater over equatorial regions than anywhere else in the world. In other words, the decrease of temperature with altitude continues to a much greater height within the tropic than elsewhere, and this explains the fact that the lowest temperature ever registered in the atmosphere was met with almost exactly over the equator, viz., —84.3 deg. C. (—119.7 deg. F.), at an altitude of 19,260 meters (about 12 miles), at Shirati, on Victoria Nyanza, August 5th, 1908.

This was one of many interesting results of the remarkable series of sounding-balloon ascensions executed in equatorial Africa by the expedition under Berson and Elias, sent out by the Royal Observatory of Lindenberg, the complete report of which has just been published by the observatory.

## ENGINEERING.

**Concreting** is proceeding so satisfactorily at the Gatun locks that in the upper or lake-level tier, which formed the subject of recent illustrations in our columns, about one-half of the work is completed. The grand total of excavation done on the canal during April was 2,632,468 cubic yards.

**In a recent paper,** Rear-Admiral Bacon of the British navy, discussing the probable battleship of the future, arrives at the conclusion that the race between gun and armor, which has been going on for over half a century, has been decided, for the moment, in favor of the gun, nor is there any indication of there being a chance of improving the armor and strengthening general construction, so as to render ships reasonably immune from armor-piercing projectiles.

**The fact** that the excavation of the Panama Canal through the Culebra range of hills has set in motion a mass of 2,000,000 cubic yards of material, which is sliding into the excavation apparently on an inclined substratum of clay, serves to illustrate one of the many advantages of the present high level canal over one at sea level. The sea-level cut would have been carried eighty feet deeper, and the slides would have been, in all probability enormously greater. The material will have to be removed, but outside of the additional expense, no ill effects are to be apprehended.

**The Hudson and Manhattan Railroad Company** is to be congratulated on having introduced some all-steel baggage cars for the transportation of baggage between the several steam railway terminals served by its system. The sides of the cars are provided with roller curtains. There are also folding aprons, which can be let down to bridge the gap between the loading platform and the car. Eight loaded baggage trucks can be wheeled directly into the cars, an arrangement which eliminates much handling and trucking and facilitates quick loading and unloading.

**It has been** determined that the sinking of the United States floating drydock "Dewey" at Olongapo in the Philippines was due to an omission to close the intake valves. Accidents of this character occasionally occur, and one is reminded of the sinking of the "Texas" at the Brooklyn navy yard, which happened shortly before the Spanish American war. At the time of her launching, the "Dewey," 500 feet in length and 135 feet in width, was the largest floating drydock in the world. She will probably be raised intact.

**Asked for his opinion** regarding the probabilities of the introduction in the near future of gas engines as a motive power for driving large steamships, Sir William Henry White, for many years chief constructor of the British navy, recently stated that in his opinion the difficulty of high temperatures for the present effectually barred the way. If this problem could be mastered as to its mechanical features, it might be possible to utilize gas engines of 20,000 horse-power; but the proposals to drive battleships with gas engines "are so far only schemes."

**The plan** for opening a central avenue, one hundred feet wide, between Fifth and Sixth avenues from Eighth to Fifty-ninth streets which is being actively favored by Mayor Gaynor, would undoubtedly relieve the congestion on Fifth Avenue, to say nothing of providing the city with a magnificent thoroughfare through one of its most important districts. The estimated cost of forty million dollars, however, is prohibitive. There are other public improvements, such as subways, municipal buildings, and public schools, that are more urgent than this.

**An extraordinary** record was made at target practice recently by the new battleship "South Carolina," of eight 12-inch guns, which has been in commission only three months. Coxswain J. R. Edwards, 21 years old, who is in his first enlistment, made a record with the 12-inch guns in the vessel's No. 4 after turret of 16 bull's eye target hits out of 16 shots in 4 minutes and 51 seconds. The hits per gun per minute for the whole 12-inch battery were 1.01, and 55 of 60 12-inch projectiles hit the bull's eye. Furthermore, three of the four turrets on the ship made 100 per cent of hits.

**The advantages** of oil over coal were illustrated in a recent trip of the "Yale," one of the 22-knot passenger steamers which run between New York and Boston. The trials were so satisfactory that oil will be used exclusively on these ships in the future. Outside of the absence of smoke from the funnels, is the complete abolition of noise and dust due to coaling. Formerly, the "Yale" burned on a round trip 235 tons of coal, which took eight hours to get aboard; in future it will take only an hour for an oil barge to pump into the ship's tanks the 44,000 gallons of oil which will serve for the round trip. The principal saving, amounting to $500 a month, is due to the fact that eight operators do the work in the boiler room, where formerly forty-eight stokers were necessary.

## ELECTRICITY.

**In their tour** of the Great Lakes this month, the members of the Chicago Association of Commerce will be able to keep in telephonic communication with their Chicago offices. Their steamer, the "Theodore Roosevelt," is fitted with a wireless telegraph outfit, and also with a telephone system which may be connected with land lines at the docks where the steamer puts up.

**The indirect system** of illumination, which consists in casting the light of a lamp against a white surface, such as a ceiling, and having it reflected and diffused thereby, is rapidly growing in favor. In order to make this system possible with the use of arc lamps an improved type of arc lamp has been devised by an English concern, in which the carbon-feeding mechanism is placed below the arc. The result is virtually an inverted arc lamp, and there is practically no obstruction to the light passing upward except for the means of suspension from the ceiling.

**This fall** the annual meeting of the Illuminating Engineering Society is to be held at Johns Hopkins University. Arrangements have been made for an extended course of lectures on the subject of illuminating engineering, immediately after the convention. Thirty six lectures will be given from October 26th to November 8th, and facilities are provided for practical demonstrations and laboratory work in connection with the subjects taken up. It is hoped that these lectures will result in a course of study in this branch of engineering for undergraduate technical schools. It is realized that there is a scarcity of practical illuminating engineers.

**In Norway** and Sweden the question of hydro-electric generation of power has recieved a great deal of attention from the fact that there are so many rivers in these countries capable of such development. Contrary to the custom in this country it is the practice in Sweden to couple generators directly with slow speed turbines. One interesting form of turbine generator consists of two wheels, the shaft of one passing through the hollow shaft of the other. The wheels turn in opposite directions, and one shaft carries the armature, while the other carries the fields of the generator. This virtually amounts to doubling the speed of the generator or reducing the number of poles. Hydraulic thrust bearings are used. At Korsnas, Sweden there are four pairs of turbines on a single shaft developing 420 horse-power. The fall is but six feet and the wheels make but 107 revolutions per minute. At Stangfjorden, in Norway, where there is a fall of 200 feet, a single wheel is used producing 1,300 horse-power running at a speed of 300 revolutions per minute.

**Mention was recently** made of a combined stethoscope and telephone relay, by which the heart beats of a patient in London could be heard in the Isle of Wight. In a paper read before the British Institute of Electrical Engineering, S. G. Brown the inventor described the construction of this relay. It comprises a gap of 0.000,000,5 centimeter between platinum electrodes. The current of a dry cell will flow across this microscopic break, but any slight variations in this distance will vary, greatly, the current passing across the gap. The principal difficulty encountered was the question of preserving a gap of such microscopic proportions. It was evidently impossible to maintain the gap mechanically, but a system has been devised whereby the gap is automatically maintained by the current itself. Despite the delicacy of the adjustment, the relay may be turned upside down without affecting the gap. With this relay the fluctuations in feeble currents may be magnified twenty fold. An illustrated description of this relay and stethoscope will be published in next week's issue of the SCIENTIFIC AMERICAN.

**The wireless** telegraph station which has been recently erected by the French government on the Channel coast at Boulogne is of interest from the fact that it represents the first official application of the Bellini Tosi system of directed waves. The new plant at Boulogne is operated by the French Postal and Telegraph department and is laid out so as to be operated either by the usual method or by the Bellini Tosi system. Accordingly the plant has an ordinary vertical antenna and an antenna for directed waves. These aerial systems are supported by four structural iron towers 165 feet high placed at the corners of a 260 foot square. Four cables connect the tops of the towers, and the Bellini-Tosi antenna consisting of two groups of wires, is suspended from these. Each group is formed of two vertical antennæ converging towards the top, each having six parallel wires spaced 12 feet apart. These antennæ form a triangle with a horizontal section near the ground and two inclined wires. At the top the antennæ are 260 feet apart and at the bottom 420 feet. The new station is working with the French stations of Saintes-Maries, on the Mediterranean coast, and also with the Algiers post.

## SCIENCE.

**Prof. Eduard Friedrich Wilhelm Pflueger,** who died on March 17th at the age of 81, at the end of over sixty years of single-minded and unswerving devotion as a student of physiology, was best known to the scientific world by the 131 volumes of Pflüger's Archiv. To that monumental publication many a distinguished scientist has contributed. Pflüger himself made a special study of the mechanism of spinal action in the frog and the law of reflex action as studied upon the decapitated animal was one of his earliest investigations. His work on physiological consumption in living organisms has played an important part in our knowledge of the chemical respiration of the tissues.

**During** the past three months the United States Weather Bureau has introduced a simplified form of weather map, known as the "commercial weather map," for publication in the daily newspapers, and this now appears regularly in about forty papers. This is an innovation of far reaching importance as it gives a much wider circulation to the information contained in the map than it has had heretofore. While the matter is still in the experimental stage, it appears altogether probable that the newspaper maps will ultimately replace the maps now published by Weather Bureau stations throughout the country resulting in a great saving of expense to the government and the advantage to the public above mentioned.

**Prof. Kronacher** has studied the power of yohimbin to increase the flow of milk of cows and sheep. The results prove that the yield of milk is increased during the administration of yohimbin, but the increase is not sufficient to make an extensive use of yohimbin as a galactogogue commercially profitable in the case of healthy animals. In the case of a cow, whose yield of milk was diminished by an inflammation the disease was greatly mitigated by the treatment, and an increased yield of milk followed. Many similar instances were observed. In no case did any injurious results follow the administration of the medicine. No experiments have yet been made on the influence of yohimbin as a galactogogue in the human species. In this case the question of expense is of less relative importance and the favorable results obtained with animals appear to promise a successful outcome.

**The alloys** of iron with metals other than those which enter into the composition of cast iron and steel have been little studied. In order to ascertain if any of these alloys possess useful electrical properties, Burgess and Aston have made a series of experiments with alloys of iron with arsenic bismuth, and antimony. The iron which they employed was obtained by the electrolysis of very pure Swedish iron. The metals were melted together in the electric furnace in a crucible of magnesia. The alloys were cast into bars which were subjected to various thermal treatments, and were investigated for magnetic permeability and hysteresis. The results show that the presence of antimony in iron always injures the mechanical strength of the metal, and sometimes makes it worthless. Small quantities of arsenic improve the magnetic properties of iron and increase its electrical resistance. Bismuth produces the same effect but it must be added in larger quantities than arsenic.

"**The sun** glows in the Lion" says Seneca meaning that when the sun enters the sign of Leo, at the summer solstice the highest temperature of the year is experienced. We may say, on the other hand that the Babylonian astrologers thousands of years ago placed the king of beasts the fiery and ferocious lion in that part of the zodiac which the sun enters at the summer solstice. The constellation which is called Leo bears very little resemblance to the outline of a lion. Probably the name was originally applied only to its principal star, Regulus. It is to this constellation in the zodiac that we owe the countless water-spewing lions' heads, which are found in ancient and modern fountains, because in the latter part of July, while the sun is still in the sign Leo the Nile is at its highest level. Furthermore the lion's head with widely open jaws is in itself very suitable for the mouth of a fountain or water spout. This decorative *motif* was employed universally throughout the Greco-Roman world. Lions heads are found used in this way at Athens, Ephesus, Olympia, Agrigentum, and countless other places. It is not quite certain that this employment of the lion's head originated in Egypt, Curtius describes an Assyrian bas-relief from Balran, showing water streaming from a ring-shaped vessel. A lion stands as if on guard on either side of the fountain. The water clock, which was used in judicial proceedings, had the form of a lion and a name which means the guardian of the stream. Hence the idea of protection may have been the origin of the association of lions with fountains, and this custom may have originated in Asia.

# THE OCEANOGRAPHIC MUSEUM AT MONACO

BY DR. ALFRED GRADENWITZ

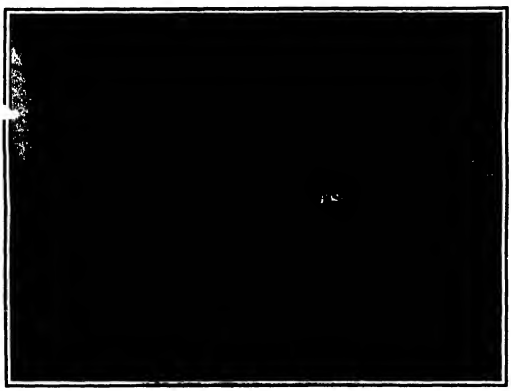
The Prince of Monaco besides being the ruler of one of the smallest though most charming countries, has achieved fame in the world of science, has endowed his principality with a scientific institute unique in its kind, viz, an oceanographic museum destined to contain not only the enormous collections brought home from his own voyages of discovery, but, generally speaking, everything relating to the investigation of the sea and its inhabitants, animal and vegetable

This museum which was solemnly inaugurated some weeks ago is situated in a site of surpassing beauty on a precipitous rock dominating the Mediterranean, close to the famous St Martin Gardens thus allowing of the installation of two basement stories, which open immediately on the sea for the sake of certain scientific investigations The foundation works of the building had obviously to be most elaborate, the more so as some of the pillars start nearly from the level of the sea

The building, 100 meters in length, is of a most imposing appearance, and is a masterpiece from an architectural point of view Each of its monolith columns 8 meters in length, is 18 tons in weight Most of the motives of decoration are derived from the fauna of the ocean

When entering the ground floor, we are at first struck by the imposing mosaic floor, on which is represented—likewise in mosaic—the Princesse Alice, the yacht on which the Prince has achieved his most important scientific cruises Everywhere around the hall are seen ornamental subjects representing fishes and other inhabitants of the ocean On both sides a monumental staircase leads up to the first floor

The museum of Monaco.



Skeletons of whales, narwhals, and other ocean giants.

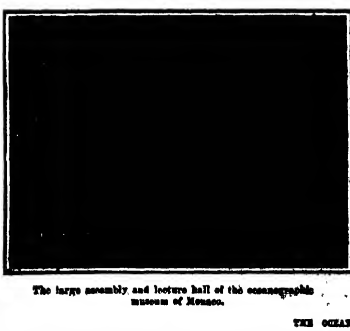
After passing through a huge glass-paned door, we enter a large assembly hall, 7 meters high, adorned with four beautiful columns of Brescia limestone, from the ceiling of which is suspended in the center an electric luster representing a medusa, whereas each of the four angles is taken up by a smaller luster forming a glass sphere adorned with long prisms reminding of sea anemones, star fishes, and other radiata In front is seen a large statue of the Prince, representing him on board his yacht searching the horizon

The western hall is set apart for lectures, congresses, and other assemblies, a large part of its back wall being taken up by an artistic painting representing the 'Princesse Alice' on an intensely blue and somewhat agitated sea.

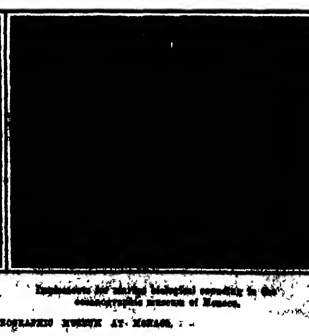
The eastern hall is taken up provisionally by sundry collections of zoological subjects and oceanographical instruments, but is destined particularly for the collections brought home from the Prince's voyages, which include the rarest and most beautiful specimens. In fact, the wonderful equipment of the "Princesse Alice has allowed the sea to be searched down to a depth of more than 6 000 meters, while four expeditions in Arctic districts, beyond 80 deg northern latitude, have yielded specimens of the Arctic fauna, suggestive of the most interesting comparisons with those of the Mediterranean and the Northern Atlantic respectively

Whereas these zoological collections are housed in the right hand half of the hall, the exhibits on the

(Concluded on page 489 )



The large assembly and lecture hall of the oceanographic museum of Monaco.



Implements for marine biological sounding in the oceanographic museum of Monaco.

Statue of Prince Albert in the museum.

# THE NAM-TI BRIDGE

## A REMARKABLE NEW RAILWAY BRIDGE IN SOUTHERN CHINA

The Yunnan Railway Company is completing the construction of a line which will connect Laokay, a frontier town of the French Asiatic possessions, with Yunnansee, the capital of Yunnan, and will be of great importance in developing the commerce of Indo-China and Tonkin. The construction of this railway through one of the most tightly closed provinces of China has been greatly impeded by the climate, the difficulty of transportation and the incompetence of native workmen. Owing to these difficulties, the original plan of crossing most of the streams by means of stone viaducts was abandoned after a few unsatisfactory experiments, and it was decided to employ, as far as possible, steel bridges, of various types to suit local requirements, and so designed that they could be constructed in parts at the Batignolles works in Paris, forwarded to their destinations, largely by rail, as the line advanced, and quickly put into place. The bridge thrown over the Nam Ti River and the peculiar methods employed in its construction are here described and illustrated. At this point the river flows through a deep gorge between nearly vertical cliffs which the railway pierces by means of two curved tunnels, at a level more than 300 feet above the bed of the stream. The width of the chasm at this level of the railway is about 220 feet. In these conditions the construction of a simple truss bridge of a single span would have entailed much labor expense and delay, owing to the necessity of working underground and of greatly enlarging one of the tunnels in order to obtain room for the partial assembling of the heavy and deep truss required. It was desirable, furthermore, to begin the construction of this comparatively large bridge before the railway had been extended to the gorge, in order to avoid any interruption in the progress of the line. Consequently, owing to the entire absence of wagon roads, the greater part of the material and machinery had to be carried a considerable distance on the backs of mules and men, in parcels not exceeding 8 feet in length or 175 pounds in weight. These considerations determined the choice of the type and method of construction shown in the accompanying illustrations.

The superstructure of the bridge is composed of [illegible] independent [illegible] trusses, the ends of which [illegible] abutments at the mouths of the tunnels and on three intermediate supports, [illegible] by the [illegible] of [illegible] supporting trusses of triangular profile and by two [illegible] which rise from the [illegible] of the supporting [illegible]. The lower ends of the supporting [illegible]

THE NAM-TI BRIDGE.

on abutments constructed on artificial ledges on the walls of the gorge about 60 feet below the railway. The distance between these abutments is about 180 feet but the total length of the superstructure of the bridge is about 220 feet.

The supporting trusses were shipped from France in parts small and light enough to be carried by men and mules, while the upper trusses, the pylons and the joint connecting the supporting trusses were sent out in riveted sections of comparatively great size and weight which could be transported only by rail, as it was designed to have the railway completed to the gorge by the time the construction of the supporting trusses would be finished.

The supporting trusses are attached to their abutments as they are to each other by movable joints. They were assembled in nearly vertical positions and their upper ends were subsequently lowered until they met.

Each of the supporting trusses is composed of two single triangular trusses the planes of which are inclined symmetrically to the vertical at angles of 14 degrees. These trusses are about 25 feet distant from each other at their lower and outer ends and about 11 feet at their upper and inner ends. The straight bottom chord of each single truss is composed of two vertical plates about 2/5 inch thick and 14 inches deep separated by an interval of 10 inches suitably connected and stiffened by L-bars or angle plates. The top chord, which forms a broken line is of similar construction but variable section, and is reinforced above by transverse plates about ½ inch thick. The truss is completed by pairs of light L-bars placed normally and obliquely to the bottom chord. The two single trusses of each supporting truss are connected by cross braces in the planes of the normal bars and in the three planes of the bottom and top chords.

The lower and outer end of each single truss is supported on a stone pier by means of a ball-and-socket joint of steel. The concave member of the joint is attached to the truss, the convex member is fitted to the pier by means of a bed plate and adjusting wedges. The radius of curvature of the joint is about 6 inches. The upper and inner ends of the trusses are connected by hinge joints having pins of forged steel, 7.6 inches in diameter. These pins are perpendicular to the planes of the single trusses and consequently, are not horizontal but the amplitude of oscillation is so small that this slight inclination does not impair the freedom of the joint.

Although the weight of the bridge is sufficient to insure transverse stability in the

strongest winds, additional resistance is given by steel bars attached to masonry anchorages and to the rock.

The superstructure of the bridge is composed of two terminal spans 51.6 feet and 71.7 feet long, and two intermediate spans each 48.2 feet in length. The trusses have a uniform depth of about 6½ feet. The floor beams which connect the top chords of the two single trusses are 16 inches deep and about 1/3 inch thick.

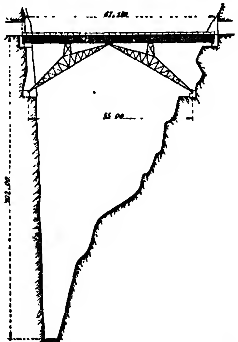
The most interesting feature of the Nam-Ti bridge is the method by which it was erected. Before the various parts of the supporting trusses had reached the tunnel nearest the French possessions a windlass was set up over the mouth of each tunnel and the cables of these windlasses were joined together so that material suspended from the junction could be carried across the gorge by unwinding one cable and winding up the other.

The supporting trusses were partly assembled into a few large sections in the tunnels. These sections were then hoisted to their proper places in the trusses which were erected in a nearly vertical position and supported by the ball-and-socket joints at their lower ends and by temporary stays and timbers. The terminal section of the truss, including the socket, was first placed in position on the ball of the joint, which was anchored securely to the rock. The outer halves of the upper chords with the ties and braces lying in their common plane, were next erected. The rectangular frame thus formed, which leaned against the cliff and was also stayed by ropes and timbers was then attached to the interior of the tunnel by two tackles strong enough to prevent it from being dragged forward by the weight and leverage of the remaining parts as they were added, and to maintain the completed truss in its vertical position. This frame then served as a scaffold for the assemblage of the bottom chords of the truss and their attachments. In this position of the truss the bars which are perpendicular to the bottom chords were so nearly horizontal that they formed convenient supports for the few planks on which the workmen stood. After the bottom of the truss had been completed the inner halves of the top chords were assembled in the same manner, some of their auxiliary parts being temporarily omitted in order to lighten the inner ends of the truss. The parts were temporarily joined by means of lathe-turned bolts in order to secure the greatest possible precision, but the construction of the supporting trusses was so far in advance of that of the railway that it was found possible to replace most of the bolts by rivets before the track had been extended to the gorge. Meanwhile in order to save time, a file of coolies, marching five feet apart, carried through the tortuous mountain passes for more than 12 miles, the two heavy chains, each 900 feet long, which were employed in lowering the supporting trusses to their final positions. The other machinery required for this purpose, as well as the sections of the upper table of the bridge, was brought by rail.

The lowering was accomplished by means of two great pulley blocks, anchored to the face of the cliff above the tunnels and connected by the two long chains with two similar blocks attached to the upper ends of the trusses. The chains were first drawn taut in order to slacken the temporary tackles attached to the interior of the tunnels and allow their removal. The chains were then slowly paid out, by means of windlasses provided with brakes, allowing the two trusses to turn around their outer ends, like the halves of a bascule drawbridge, until their inner ends came together. In order to facilitate this operation, both trusses carried sights at their inner end, and one of them, which was lowered a little after the other, bore both parts of the hinge joints by which the trusses were to be connected.

The omitted parts of the trusses were then added, a bed plate was constructed over their junction, and a pylon, which had been partly assembled in frames of two posts, was erected over the middle of each truss.

The upper table of the bridge was assembled, as a continuous truss, in a straight and not very long excavation in the first tunnel. As its construction progressed it was moved forward with the aid of rollers placed on the two pylons and the junction of the supporting trusses until it had been completed and its forward end had reached its abutment on the opposite side of the gorge. The connections between the four spans were then removed. The construction of the bridge was commenced in March, 1908, and was



Side view of the bridge and section of the gorge, with dimensions in meters.

completed in November of the same year.—G. Bodin, in Le Génie Civil.

---

At the Höganäs coal mines in the south of Sweden, states the Iron and Coal Trades Review experiments have been carried on for some time with the smelting of fine iron ore by means of Swedish coal. These experiments were at first conducted with a Gröndal furnace using coal of an inferior quality, for which it was desired to find an outlet. Later the chief director of the Höganäs coal mines undertook to conduct the experiments independently, and it appears that he has now obtained favorable results, and that sufficient data have been collected to allow of exact calculations and estimates being made. The owners of the Höganäs coal mines—the Billesholm Aktiebolag—have, in consequence, resolved to build a furnace with a capacity of 15,000 tons of fine iron ore per annum. When this furnace has been tested in practice with the view of discovering possible faults, the intention is to erect nine other furnaces of the same size and capacity.

The completed structure; the rails of which are 331¼ feet above the river.

One of the supporting trusses, as erected, in a vertical position.

THE NAM-TI BRIDGE.

**Recent Spectroscopic Study of the Sun.**

The physical interpretation of the changes produced in the lines of the solar spectrum, by terrestrial weather conditions and by passing from one to another point of the sun's disk, is still under discussion. Whittaker refuses to attach any definite significance to changes of temperature occurring in the stormy solar atmosphere, nor does he admit that the peculiarities of spark spectra are characteristic of elevated temperatures. Electric vibration of atoms may be excited in a cold gas, as is proved by the aurora. Whittaker attributes the observed changes in the spectrum to great pressure. Cortie and Evershed, on the other hand, defend the usual interpretation, which attributes the changes to high temperature, radial velocity and chemical action. Evershed does not admit that pressures much greater than atmospheric can exist in the sun, even at the bottom of the reversing layer. This opinion is based upon the sharpness of spectral lines in general. But the hypothesis implies that in the sun gravitation is everywhere opposed by repulsive forces.

Until recently the spectro-heliograph was applied chiefly to the lines *H* and *K*. Thus were obtained images of the flocculi, those bright clouds of calcium vapor which almost cover the sites of the spots and faculæ. Since 1908, following the example of Hale, the red line of hydrogen, which shows entirely different forms, has also been employed. This has led to the discovery of long dark filaments, which normally persist for several weeks, but which sometimes disappear or change rapidly near very active spots. According to Deslandres these filaments represent tornadoes with horizontal axes. They are exhibited especially by the middle part of the line *H* α, which corresponds to the upper limit of hydrogen vapor. The marginal portions of the same line show dark flocculi, which are reversals of the calcium flocculi.

The photographs made by Hale, at Mt. Wilson, with this same line, show the spots surrounded by cyclonic structures, which exhibit opposite rotations in the north and south hemispheres. These spirals are far less frequently observed in ordinary photographs. Can they be trajectories of material particles? The first evidence, furnished by Hale, consists in the doubling and the polarization of the spectral lines in the interior of the spots. These phenomena suggest the circulation of electrified matter in a magnetic field. Evershed sought further evidence by placing the slit of the spectroscope across a spot near the sun's limb. In this case radial velocities in opposite directions should be found on opposite sides of the spot. Instead of this, however, Evershed found numerous and persistent indications of a tangential movement, always directed from the center of the spot. These results were obtained chiefly with the lines of iron. Possibly both movements coexist at different levels, the whirlwinds in a stratum of hydrogen, the centrifugal flow in metallic vapors beneath.

Secchi, who discovered that the dark lines of the solar spectrum become bright or reversed in a narrow stratum at the base of the chromosphere during a total eclipse, contended that this reversal could be observed at ordinary times. Hale and Adams have confirmed his view by photographing the reversed spectrum. Their success appears to be due to the very delicate adjustments which enabled them to keep the slit of the spectroscope accurately tangent to the sun's limb. The wave lengths of 124 of the lines were measured and were found exactly equal to those of the corresponding dark lines of the ordinary spectrum. This perfect agreement could not be expected if, as Julius suggested, the bright lines are due to the light of the photosphere, affected by anomalous dispersion.

---

To blacken light woods make a preparation of an ounce of borax, dissolved in a quart of water, with two ounces of shellac. The liquid is then to be boiled until a perfect solution is obtained, then stir in two teaspoonfuls of glycerine, and complete by adding a sufficiency of soluble aniline black to completely darken the liquid, which will now be ready for use.

### Instruction in Aeronautics at the University of Paris.

A Chair of Aeronautics has been established at the University of Paris by M. Basil Zaharoff, and is occupied by Prof. Marchis, who has announced the programme of his course of lectures. The professor begins by replying to the criticism that M Zaharoff's endowment would have been employed far more usefully for the development of aerial navigation if some direct encouragement had been given to constructors, who are compelled to make very costly researches, or to the brave aeronauts who risk their lives in these experiments The empiricism which necessarily rules in the beginning of every industry should now be superseded by a methodical and rational interpretation of observed facts. The object of this lecture course will be to expound as logically as possible the results which can fairly be considered as certain. Without entering into very recondite theoretical considerations, the lectures will still be far from "popular" or elementary Finally, the development of the special aeronautic library already possessed by the University, and the formation of a collection of small models of aeroplanes and dirigible balloons, will supplement the instruction given by the lectures. The professor will not confine his attention to theoretical speculations and laboratory researches, but will follow in detail the experiments of constructors and the trial flights of aviators, noting in each case the progress achieved and endeavoring to account for the failures

### Scientific American Prizes for Inventors.

The Scientific American offers $100 in three prizes, to be awarded to the inventor who gives the best account of how he conceived his invention, how he developed it in actual practice, and how he succeeded in selling it This sum of $100 to be distributed as follows $50 to the best account, $35 to the second best account, $15 to the third best account.

There is no limitation as to subject matter of the invention In other words, the invention may be a household utensil, a game, a piece of electrical apparatus, an improvement in railway construction, a metallurgical process, etc. The following conditions, however, must be observed

1 The invention must be patented

2 The inventor must have actually sold his patent, and the invention must have been commercially introduced

3 The account of the inventor's success must not be longer than 800 words.

4 The composition, letter, or article must be typewritten on one side of the paper only

5 The inventor must sign his offering with a pseudonym, and inclose it in a sealed envelope, upon which the pseudonym is written A second sealed envelope must be provided, bearing on the outside the pseudonym under which the offering is submitted, and containing the real name and address of the contestant

6 Contestants must address their offerings to Inventors' Prize Editor, Scientific American 361 Broadway, New York city

7 The contest remains open until August 15th, 1910 Judges will select the essays which, in their opinion, have won the three prizes and give them to the Editor of the Scientific American, who will thereupon open the sealed envelopes containing the true names of the contestants, and notify the winners of the prizes

8 The Editor of the Scientific American has the right to publish the prize winning articles or letters as well as those which may not receive prizes

9 Unsuccessful letters cannot be returned It is thereupon urged that the contestants preserve copies of their contributions.

### Official Meteorological Summary, New York, N. Y., May, 1910.

### REDUCTION-GEAR TURBINE TESTS.

To the Editor of the Scientific American

Your article "A Way Out of the Marine Turbine Dilemma," in your issue of the 12th of February places before the general reader throughout the world an epoch-making invention There can be little doubt as to its great value, and any discussion that hastens the proof thereof may be welcome

You refer to the difficulty of ascertaining the actual horse-power of a turbine as a factor of uncertainty in the calculation of the efficiency of the combination, and suggest that a reliable check upon the results given is afforded by computations based on the rise of temperature of the oil But the heat causing this rise of temperature is, at the same time, communicated to the large surrounding masses of metal, and the heat thus taken away from the oil should be calculated, if possible, or allowed for

There is another way less open to question for measuring the loss of power due to friction Let the driven shaft be made the driver at 300 revolutions per minute by a reciprocating engine directly coupled thereto, so that the pinion shall be driven It will then be easy to apply a brake to the pinion shaft, and ascertain the power transmitted upon a definite basis of comparison with the power exercised on the other shaft

The results of such a reciprocal test will not merely be "well within reason" but will convince the world They will certainly be most satisfactory, but below an efficiency of 98 %
G Strickland

Perth, Western Australia.

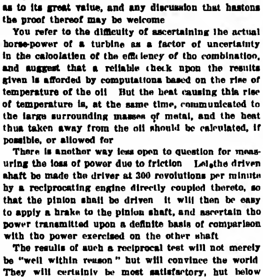
### The Safe Knot in Case of Fire.

To the Editor of the Scientific American

In your issue of May 28th, page 441, is a figure which would be liable to lead to harm if followed in case of fire The right hand upper illustration shows a "granny" knot, which is a loose or slipping knot The one which should be used is the "square" knot, in which the end and strand both pass *below* the loop, or both above it, instead of one above and one below as shown The square knot will not slip

F H Hall.

[There can be no doubt that our correspondent is



THE CORRECT WAY OF TYING

correct. The "granny' knot would be unsafe for the serious use to which it would be subjected in case of fire We therefore publish the foregoing diagram in order to correct any liability to mistake —Editor ]

### New Cometary Theories.

Neither the comets seen for the first time in 1909, nor the periodic comets of Perrine and Winnecke which reappeared nearly in their computed places, offers any special interest Halley's comet reappeared in the position calculated by Cowell and Crommelin It was first detected in a photograph made by Wolf, at Heidelberg, on September 11th but was subsequently found on a plate exposed by Keeling on August 24th Its brightness increased slowly until the end of the year Its spectrum, first observed in December, showed the absorption bands of nitrogen and cyanogen, with indications of self luminosity due to incandescent gases

The past year is marked especially by the results of the retrospective study of the spectroscopic and direct photographs of Morehouse's comet (1908 $C$), which was barely visible to the naked eye This comet exhibited several divergent bright tails accompanied by streamers darker than the sky, as if the space surrounding the comet were filled with luminous matter Subsequently, the tails bent and crossed, and Melotte observed a diminution of brightness at the point of intersection, as if one tail absorbed the light of the other Several times the tail appeared to break up into knots, which formed new envelopes and moved away from the head with increasing velocity Comparison of successive photographs showed that the compound tail opened and closed as if the whole structure were rotating about a central axis. The stereoscopic combinations made by Barnard appear to indicate the presence of tails of helical form, but Barnard suggests that this effect may be due to changes of form in the intervals between exposures Crommelin observes that the apparent rotation of the tails may also be an illusion It is sufficient to suppose that the head rotates slowly and projects particles rapidly in a plane which follows the rotation If the tails represent the trajectories of particles, forces emanating from the head and from other points must co-operate with solar attraction and repulsion The occurrence of four successive outbursts of activity suggests the influence of a medium of variable constitution, formed by particles ejected by the sun and made visible by the passage of comets, either by electrification or by carrying cometary matter with them This hypothesis would explain the presence of cyanogen and certain other lines in the spectra of nearly all comets On this theory the apparent boundary of a comet's tail like that of a flame, would be simply the locus of a change of physical state

In the spectrum of this comet, E C Pickering found six absorption bands corresponding to the principal lines of hydrogen At Meudon and Juvisy a faint continuous spectrum indicating self luminosity, was observed Deslandres regards the three pairs of bands as doubles, due to the Doppler effect and deduces for the cometary matter a velocity of more than 1,200 miles per second but the presence of a strong single line in addition, leads Campbell and Albrecht to reject this interpretation

### The Current Supplement.

A thoughtful yet popularly written article on Heredity by Prof W E Castle of Harvard University opens the current Supplement No 1797 The article shows that before any serious attempt can be made to improve the human race considered as an assemblage of animals possessed of certain desirable physical and intellectual attributes it is obvious that we must know something about heredity in general and how, in particular each of the desired physical and intellectual attributes is produced In his article he reviews briefly some of the problems which the study of heredity presents and some of the results obtained from their consideration —Sir William Crawford concludes his excellent consideration of Irish linens and their manufacture —Shellac or lac is one of those aids to civilization about which there has tended to be an atmosphere of mystery and romance Mr G Clarke Nugent removes much of this mystery in a strictly scientific account of shellac and the lac industry —A Roze's instructive article on how to build a profile puppet show is concluded —A critical consideration of the Mallet locomotive in service is published —The chemical regulation of the processes of the body by means of activators, kinases, and hormones is discussed by Prof William H Howell of Johns Hopkins University —Mr William E Stark's paper on Measuring Instruments of Long Ago is concluded —We are very apt to regard the tail of an animal as merely "the other end" of the body but Nature seems to have early esteemed the member highly and to have made it her most efficient instrument of locomotion Many curious facts about these uses of tails are described by Mr James Newton Baskett —Mr W F Denning summarizes our knowledge of the planet Mercury —The usual Electrical Notes Engineering Notes and Trade Notes will be found in their accustomed places

### Wanted: Information About Dishonest Patent Schemes.

The Scientific American has always made a practice of exposing the snares and devices of the patent promoter as well as the fraudulent patent attorney Although the subject is by no means new to the readers of the Scientific American it is one of which all inventors should be thoroughly informed The Editor of the Scientific American would like to receive from readers of this journal, letters in which they narrate their personal experiences with dishonest promoters and attorneys Such letters will be published in due course and should not only be of interest in themselves but should serve as a warning, thereby protecting others against such snares.

**Antique Siamese Bronze** (Without Bronze Powder ) —This is a greenish-black coating, with inlay of green patina Rub chrome green and zinc white to a greenish white color with turpentine oil, mix with copal varnish and apply to the object, coating the hollow portions especially If there is rich decoration coat this all over and dry Now rub green cinnabar graphite, and some black pigment to a greenish black color with turpentine oil mix with copal lacquer and coat over all the raised portions leaving the hollows untouched, so that the first layer in the hollow portions will have the appearance of copper oxide. Glaze after drying, with spirit lacquer Handle the brush just as in ordinary bronzing

# THE ALBANY-NEW YORK AEROPLANE FLIGHT

## HOW CURTISS COMPETED FOR THE SCIENTIFIC AMERICAN TROPHY AND THE NEW YORK WORLD PRIZE

OF the three attempts that have been made to fly from New York to Albany, or *vice versa*, the first two were made last fall by dirigible balloons, and were unsuccessful, while the third attempt was made recently by an aeroplane, and resulted in a brilliant prize-winning flight.

The New York World, which so generously donated a prize of $10,000 last summer for the performance of this feat during the Hudson-Fulton celebration afterward extended the time within which it could be competed for to October 10th, 1910. Only a few weeks ago after the exciting aeroplane race of Paulhan and White from London to Manchester, England, for the $50,000 prize of the London Daily Mail it was decided to amend the rules and permit the making of two stops *en route*, while the time limit for the completion of the trip was set at 24 hours. As soon as the modifications were announced, Glenn H. Curtiss, the first winner of the Bennett cup race in France last year and twice the winner of the SCIENTIFIC AMERICAN Trophy, began experiments with a new and powerful biplane at Hammondsport, N. Y., with regard to landing upon water. He had already experimented last fall upon rising from the water, and, although unable to accomplish this, had attained a speed of 20 miles an hour with his small biplane resting on pontoons and driven by its air propeller and 25 horse-power 4-cylinder Curtiss aeronautic motor. It was therefore a comparatively easy matter to fit his new and larger biplane with cylindrical floats and an air-tight canvas bag running the length of the wood strut that connects the front and rear wheels.

After making a number of flights over Lake Keuka, at Hammondsport, N. Y., and landing successfully upon the water, Mr. Curtiss shipped his aeroplane to Albany and took a prospecting trip on the steamboat from the capital to the metropolis. He found practically no suitable landing places on the river banks throughout the entire journey. At Poughkeepsie, however, a mile back from the east shore, he selected a landing place on the farm of Mr. W. F. Gill. Upon reaching New York Mr. Curtiss gave notice that he would attempt to win the cash prize of the World and also the SCIENTIFIC AMERICAN Trophy for the third consecutive time, which would give him the cup permanently. He then returned to Albany to superintend the assembling of his biplane. This was accomplished in a tent pitched upon Van Rensselaer Island, a mile south of the railroad bridge at Albany. A heavy rain caused delay in assembling the biplane and kept the aviator from starting on Thursday, May 26th, while Friday the flight was impossible of accomplishment because of strong wind. Early Saturday morning Mr. Curtiss went to the island. Everything was in readiness for the flight, and the weather appeared to be perfect, but just as the aviator was about to start a wind sprang up, and he was obliged to again postpone his attempt. Sunday morning dawned bright and clear without any signs of wind, and after waiting till 7 A. M. to see if the wind would increase, Mr. Curtiss started three minutes thereafter. Circling to the north so as to pass within the city limits of Albany just below the railroad bridge, the aviator headed down the river at a 50-mile clip against a wind of 4 or 5 miles an hour velocity. He rose quite rapidly to a height of 1,000 feet, and followed the course of the river for 75 miles to Poughkeepsie. As he came in sight of the railway bridge at this point, he was flying at an elevation of about 500 feet. He increased his height somewhat as he neared this 212-foot-high structure, which he passed several hundred feet above. Three miles beyond the bridge he turned inland on the east side of the river, and landed at 8:26, on the field at Camelot which he had previously selected. The 74¼ miles had been covered in 1 hour and [illegible] minutes at a rate of more than [illegible] miles an hour. The special train which started from Albany after Mr. Curtiss [illegible]

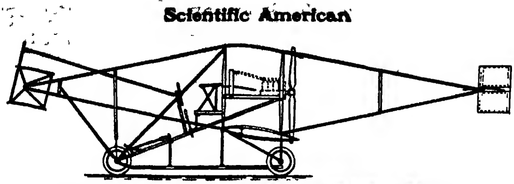
THE ALBANY-NEW YORK AEROPLANE FLIGHT.



Side elevation of Curtiss biplane, showing relative positions of planes, rudders, etc

keeping parallel with him almost the entire distance to Poughkeepsie. After he landed, however, he was obliged to send for gasoline and oil, in order to replenish the tanks of his biplane before continuing the journey. This necessitated a stop of one hour At 9:26 A. M. he re-started on his eventful flight and, soaring out over the river, he headed toward New York at a somewhat slower gait than before, owing to the curves and wind. During the balance of the journey, he maintained a height of from 500 to 800 feet. He did not fly as high as during the first part, since, in passing through the Highlands, he found that it was better to fly at a lower elevation Upon reaching Newburg Mr. Curtiss could see from the smoke that the wind had changed and was blowing from the west, or directly across his course. As the velocity was not great, however, this did not cause him any uneasiness.

Soon after passing Storm King, the 1,530-foot mountain that juts out into the river just above West Point, the daring aviator experienced a sudden down draft of air that caused the machine to drop so rapidly that it seemed to fall away beneath him At the same time, it tipped at a sharp angle to one side, owing to one end catching more of the downward current. With great presence of mind Mr Curtiss directed his front horizontal rudder sharply downward, in order to gain speed by making a dive and thus to enable his balancing planes to become effective, which, of course, they were not when in a current of air traveling perpendicular to them This maneuver was successful, and he was able to right the machine Save for this once, he had no thrilling experiences He passed over Iona island, near West Point, as shown in one of our photographs, but for the greater part of his trip he followed the middle of the river He made a practice, however, of keeping to the leeward side of the river as much as possible Thus, when Peekskill was reached, and he found that the wind had again shifted so that it was blowing from the northeast, he crossed over to the Jersey side, and followed the stream above the Palisades, When Spuyten Duyvil was reached, noticing what seemed to be a smooth, grassy field, he circled about and retraced his course for a short distance in order to land upon it. He was somewhat amazed, upon landing, to find that what had appeared from his considerable height to be level ground, was in reality a fairly steep incline, so that it was necessary for him to jump out of his machine the moment it came to a standstill, and to hold it from sliding back down the hill Afterward, when assistance arrived, he pushed the machine to the top, where there was a sharp terrace, and after making a stop of over an hour, he started off this terrace after a very short run. The machine soared off the terrace without dropping to any great extent, showing the possibilities of starting from a cliff

Mr Curtiss's second stop was occasioned by the discovery that his lubricating oil was almost gone By landing upon the north end of Manhattan Island, he would accomplish the flight from Albany to New York with but one stop, while two were allowed. Therefore, so as to make sure of winning the prize, he made the short detour and landed at 10 35 A. M — one hour and nine minutes after his start from Poughkeepsie The distance covered in this second stage was, over the course followed, 53¾ miles, so that the speed was 46¾ miles an hour The remaining 14 miles to Governor's Island was covered in 22 minutes, the second start being made at 11 42 A. M., and his arrival in front of the shed constructed for him last fall taking place a few minutes after noon On this last stage of the flight, Mr Curtiss maintained a height of approximately 500 feet. He descended rapidly as he neared Governor's Island, and skimmed over the sandy stretch of made land at a height of about 15 feet, almost till he reached the shed. One of our photographs shows him a minute or two after he alighted. At Spuyten Duyvil he left off the two cylindrical floats—one on each side of the machine below the lower plane—and thus these are not to be seen in the photograph One of the other photographs which we reproduce, however, shows these floats as used at Hammondsport. The cylinders shown in this picture are somewhat larger than those that were actually used, which were about 7 inches in diameter and 7 feet in length In several of the photographs, showing the biplane in flight, these floats can be seen projecting from the back of the lower plane Together with the air inflated bag stretched along the lower runner, they had sufficient buoyancy to keep the machine from sinking should Mr Curtiss have been compelled to alight in the Hudson An examination of his machine showed that the oil tank had sprung a leak and had he not had an indicating gage constantly before him he would not have known that his supply was rapidly diminishing, and thus he might have had his motor seiz

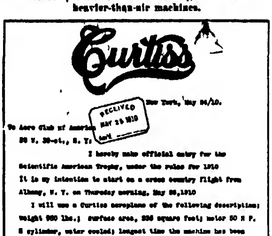
The biplane with which Mr Curtiss accomplished his epoch-making flight is very similar to the machine with which he won the Bennett Cup last fall at Rheims. It differs from the latter in having somewhat larger rudders and balancing planes, and also in the extension of the upper plane 30 inches beyond the lower plane at each end of the machine This differential plane idea was first tried a short time ago by Henry Farman, and was embodied in the machine used by Paulhan in his flight from London to Manchester It tends to give the aeroplane a certain amount of inherent transverse stability The total supporting surface in the main planes is 236 square feet, and the weight of the machine complete is 950 pounds including aviator fuel and oil As a result of this the weight carried per square foot of supporting surface is 4 02 pounds This means that the machine must travel at a speed of 40 miles an hour along the ground before it will lift In order to attain this speed, a powerful 8-cylinder motor of 50 horse-power is used The 7 foot diameter, 6 foot pitch propeller mounted upon the engine crankshaft makes 1,100 R P M while the machine is in flight, and gives a pull, when the machine is held stationary on the ground, of over 300 pounds This is, we believe somewhat better than the thrust obtained from the Gnome 50-horse-power motor used by Farman and others in their aeroplanes

The longest flight which Mr Curtiss had formerly made with his new biplane was a flight of 38 minutes duration above Lake Keuka at Hammondsport, N Y, in his try-outs of the machine The greatest care was taken in re-assembling the machine at Van Rensselaer Island, to see that all nuts were properly washered, cotter pinned, and covered with varnish, so that they would not work loose Some idea of the strains that must be undergone by a machine in flight can be had when one learns that Mr Curtiss's biplane was suddenly dropped 40 to 50 feet while in flight, by the downward current of air mentioned, and then quickly made to support itself again by a dive of considerably greater length One reason for the success that the Curtiss machine has met with is undoubtedly the neat and strong manner in which it is put together There are no bent struts and loose guy wires, such as we have noted in one of the well known foreign biplanes that was recently brought to this country, but every thing is put together in a thoroughly workmanlike manner, and consequently there have been no accidents

In making his great flight, Mr Curtiss also competed for the SCIENTIFIC AMERICAN Trophy, which is to be awarded this year for the longest cross-country flight. The first record for 1910 therefore stands at 74¼ miles but it is probable that this will be lengthened considerably before the end of the year

The average speed made by Mr Curtiss from start to finish of his flight from Albany to Manhattan Island — a distance over the course followed of 128 miles—was 50½ miles an hour Including the final leg of 14½ miles from 207th Street and the Hudson River to Governor's Island (142½ miles) this average falls to 49 14 miles an hour The actual air line distance between the starting and finishing points is 136 34 miles, so that using this as a basis, the average speed from point to point was but 47 01 miles an hour, which is the same as Mr Curtiss averaged in the Bennett Cup race at Rheims. As he no doubt covered more than 136 1 3 miles, it seems his new machine is faster than the Rheims racer with which Hamilton is making flights at Mineola, L I

The Scientific American Trophy, the first prize ever offered for successful flights with heavier-than-air machines.



Curtiss

RECEIVED MAY 25 1910

New York, May 24/10.

To Aero Club of America
38 W. 39-st., N. Y.

I hereby make official entry for the Scientific American Trophy, under the rules for 1910 It is my intention to start on a cross country flight from Albany, N. Y. on Thursday morning, May 26,1910

I will use a Curtiss aeroplane of the following description; weight 900 lbs.; surface area, 236 square feet; motor 50 H P. 8 cylinder, water cooled; longest time the machine has been operated in one flight 38 minutes.

If there are any fees connected with this entry, they will be paid on Wednesday, May 25.

Very truly yours,
Glenn H Curtiss
Hotel Astor, N.Y. City

Copy sent to the Scientific American, 361 Broadway, N. Y.

Mr. Curtiss's notice that he would compete for the Scientific American Trophy.

THE ALBANY-NEW YORK AEROPLANE FLIGHT.

## An Aerial Torpedo.

BY W G. ASTON

One of the most remarkable demonstrations of the possibilities of "wireless" has been made in London last month, when Mr Thomas Raymond Phillips a Liverpool engineer, conducted a series of experiments on a small scale with a dirigible balloon entirely manipulated and controlled from the earth These tests were made at the Hippodrome one of London's largest theaters Mr Phillips employed a dirigible on the lines of the "Zeppelin" but only 20 feet long The model complete weighed about ten pounds and the aerostat was filled with hydrogen

During the demonstration the inventor stood on the stage of the theater while his machine maneuvered about over the auditorium He had by his side a keyboard something like that of a typewriter but rather larger, and in reality composed of a number of push switches, above this was a small transmitter similar to that used in ordinary wireless telegraphy By merely pressing the keys Mr Phillips showed that he could make his dirigible do anything he liked He would press a switch over and the machine would promptly rise, the actuation of another key would produce a descent Forward and backward motion was also obtained with perfect certainly as well as circular flights and point-to-point voyages which involved very intricate steering The experiments lasted some hours but never once did the model fail to do what the inventor had announced it was about to do The most effective demonstration however, was that in which the uses of such a machine in warfare were shown The car of the dirigible had a trap door floor under the control of the operator who after maneuvering the machine over a certain spot, opened a switch which caused the trapdoor to open and allowed a number of paper bombs to fall down

The mechanism of the invention is extremely simple and one that could be made perfectly reliable In the car of the balloon are a number of coherers suited to different electric wave lengths, and these control small switches which put into and throw out of action two sets of propellers the trapdoor, and the system of lamps whereby the airship can be lit up when desired The accumulators for working the propellers and lighting the lamps are carried in the car The directional control of the airship is effected in a horizontal plane by a pair of propellers hung out from each side of the car on outriggers similar to those of the "Zeppelin" Either or both of these can be driven, and they can also be reversed either singly or together so that the machine can be steered to the right and to the left kept in a straight course, or reversed back in its own tracks without turning round

Two horizontal propellers considerably smaller than the driving screws are also attached by outriggers to the "nacelle," and provide the means for control in a vertical plane The machine is so balanced as to be approximately equal in weight to the air it displaces consequently, when the horizontal propellers are not working it neither rises nor falls, but can be made to ascend or descend by putting them in motion Thus by using one vertical propeller and the horizontal ones the machine can be caused to move in a spiral path, and by cutting out the vertical screws it can be made to rise straight up

The switches whereby the machine is controlled alter the wave length of the electricity produced at the transmitter, all the coherer switches on the airship being tuned to different wave lengths.

The demonstrations have been so successful that the British War Office have investigated the matter, and it is understood that they have taken the invention up At any rate trials with a full sized machine are shortly to be made and if these are successful the invention will be bought by the government The dimensions of the full sized war machine will be 60 feet long and 6 feet in diameter, and it will be capable of carrying nearly a couple of hundredweight of explosives while its radius of action will be well over 100 miles Its speed will be about thirty miles per hour

## MR. EDWIN GOULD OFFERS $15,000 TO THE SUCCESSFUL DESIGNER AND DEMONSTRATOR OF A SAFE HEAVIER-THAN-AIR FLYING MACHINE EQUIPPED WITH MORE THAN ONE MOTOR AND MORE THAN ONE PROPELLER.

The fac-simile letter of Mr Edwin Gould, printed on this page, in which $15,000 is offered for the best successful heavier-than-air flying machine, driven by more than one motor and one propeller, speaks for itself It may be pointed out, however, that Mr Gould, in offering his prize, has been moved by other considerations than those involved in a sporting contest. Races, long-distance flights, speed tests, and other record-breaking performances, have no doubt done much to bring the flying machine prominently before the public, but it must be admitted that, besides whetting the natural human appetite for competition and driving home the truth that the flying machine is destined to play an important part in future human affairs, such contests aid the art but little

It is Mr Gould's primary intention to further aeronautic invention and with that end in view he offers a prize not for the fastest flying machine, but for a type of flying machine which has thus far not been constructed Absolute safety must certainly be attained before a flying machine can ever become even a popular vehicle of pleasure, and the attainment of safety is the chief object which Mr Gould has in view

The conditions which will govern the novel contest which will be inaugurated by Mr Gould's magnificent offer have not been decided upon as yet They will require deliberation It is hardly likely that we shall be able to publish them for three or four weeks. In the meanwhile, the Editor will gladly consider any suggestions which the readers of this journal may make so that conditions may be drawn which will be fair and which will best serve the object of the prize.

St. Louis Southwestern Railway Company.
Office of the President,
Edwin Gould, President
165 Broadway,
New York June 2, 1910.

To the Editor,

The Scientific American,

New York City.

Dear Sir:-

In order to promote progress in aviation, I offer through the Scientific American, a prize of $15,000, which is to be given to the inventor who designs and demonstrates in this country the best heavier-than-air flying machine equipped with more than one propeller and with more than one independent motor, in such manner, that the motors can be operated together or independently.

My object in offering the prize is to encourage the invention of a heavier-than-air flying machine which will be able to continue in safety on its course, even though one of the driving devices should break down.

In order that the efficiency of the inventions may be thoroughly tested, it will be necessary to subject them to endurance tests of stipulated length of time or distance.

Full conditions governing the award of the prize will be announced in a later issue of the Scientific American,

Very truly yours,

Edwin Gould

MR. EDWIN GOULD'S OFFER OF A $15,000 AVIATION PRIZE

Kinetic energy is the power stored in a moving object which keeps it in motion By way of illustration, conceive a railway train rushing along a straight, level stretch of track, the train being driven to its power limit If the source of power, say the steam pressure, is now suddenly removed by closing the throttle, the train will continue to run or "coast," for a long distance, due to its kinetic energy, gradually reducing in speed until the energy is exhausted and the train stops.

## Recent Study of the Sun.

The sun can be studied with comparative ease even by the possessors of small telescopes, consequently the announced discoveries are numerous; but astronomers are constantly placing their chief reliance on the statistical results of precise measurements and daily and long-continued observations, and they do not accept the physical theories advanced until after a long period of probation. Even data which have been admitted and used for many years are not exempt from criticism Thus, the elements of the sun's rotation determined by Carrington fifty years ago, which are still used in the reduction of the photographs taken daily at the English observatories, have been called into question. Turner has examined the measurements made by Peters between 1860 and 1887, which fill the gap between Carrington's work and the Greenwich photographs. He reaches the surprising conclusion that the sun spots of the northern and southern hemispheres revolve about two different axes, which make with each other an angle of 6 minutes. The spots appear to be affected by a general drift which changed direction about 1885.

The hypothesis of a planetary influence on sun spots has been often discussed and generally rejected In its favor, however, may be cited the proved fact that the last maximum in the number of spots which was announced for 1905, was delayed nearly two years, and that this retardation had been predicted by Brown as a consequence of the motions of Jupiter and Saturn

The solar activity gradually decreased in 1909, as had been expected Nevertheless, a group of spots remained visible from November, 1908 to April, 1909 The group which appeared in September 1908, was found to be connected with a violent magnetic storm Lockyer's photographs made with the spectroheliograph, show that the principal spot was gradually obliterated by clouds of calcium which exhibited a cyclonic structure thirty hours before the maximum of magnetic disturbance Mitchie Smith observed that an extraordinary outburst of activity in the same spot was quickly followed by violent and prolonged agitation of the magnetic needle This group of spots affected the earth's magnetism in four successive revolutions, in two of which it produced two disturbances at intervals of five days. This fact suggests the influence of two limited and divergent beams analogous to the double tails of certain comets.

The tendency to recurrence at intervals of 27 or 28 days, is well established for magnetic storms and aurorae The question has been asked whether other terrestrial phenomena do not similarly show the influence of the sun's rotation From the records of cyclones in the Indian Ocean, Maunder finds that an interval of 28 days is of common occurrence

The first results of the total eclipse of 1908 have been published. The report of MacClean's expedition say that the corona exhibited the character, usual at intermediate epochs, of great extent in the middle latitudes, but that it was distinguished by certain features from all previously observed coronas. The coronal rays or streamers showed no connection with the protuberances.

---

The United States during February produced pig iron at a rate which equaled 31,650,000 gross tons per annum During January the rate was about 31,000,000 tons, and in December about 31,450,000 tons. In commenting on these figures, the Iron Age considers it is questionable whether the February rate will be maintained during March, since the daily capacity of coke and anthracite furnaces in use at the beginning of the month was 84,854 tons, whereas the daily rate of production for February was 86,616 tons. "It is hard to realise," the journal remarks, "that in February the production was more than 40 per cent above that of February of last year, and nearly 2 1/3 times that of February two years ago, and yet that so little metal is pressing on the market. . . . It is not surprising that a question is raised of the ability of the country to absorb pig iron at the present rate throughout the year."

# DR. ROBERT KOCH, THE FATHER OF PREVENTIVE MEDICINE

BY JOHN B. HUBER, A. M., M. D.

Dr Robert Koch died on May 27th last. To estimate the value of his work, we must consider how humanity suffered from disease before his time

Before the beneficent inoculations of Jenner, epidemics of smallpox devastated vast regions, decimating cities and wiping out whole towns and villages. Nearly every wayfarer one met was a pock-marked survivor The dreadful history of the bubonic plague is lost in the mists of antiquity To go no further back—an epidemic of it was the last of those seven plagues that afflicted Egypt. Those 50,000 Israelites and Philistines at Beth-Shemesh, and those 70,000 others were destroyed by the microscopic *Bacillus pestis* Before and since the Trojan war (in which this germ did its greatest execution), throughout the middle ages, and indeed up to our time, scores of epidemics of the bubonic plague have wrought ghastly havoc One of these, the Black Death of the fourteenth century, destroyed most miserably (so Gibbon computed) one-fourth the population of the then known world

Malaria, though not so death-dealing an agency, has nevertheless dreadfully affected the *morale* of humankind To cite but the one historic instance given by W H I Jones of Cambridge As is so often the case in history, the conquering Greeks under Alexander were conquered by the India they invaded, and its weapon was one much more potent than the sword—it was the microscopic malaria plasmodium Upon its inroads the Greeks began to "lose much of their intellectual vigor and manly strength"

Consider finally tuberculosis — consumption — which has probably always afflicted mankind At any rate Hippocrates twenty two centuries ago, wrote of it as the disease which above all others caused the most suffering and the greatest number of deaths The dreadful infections here mentioned, though more gruesomely picturesque in their ravages, have been dwarfed by consumption In the nineteenth century fourteen millions died in war, by bullet and steel and camp diseases, during the same period thirty millions succumbed to consumption From time immemorial every third or fourth adult—in some communities every other adult—has succumbed to insidious phthisis We whites have introduced this disease among negro "brethren," who die of it in greater numbers than we do, and among our Indian "wards" who are fast disappearing by reason of our tuberculosis, aided and abetted by our "fire water" Who has not, either in his family or among his friends, had to endure some experience of the "Great White Plague"? Think of it! Between adolescence and the fifty-fifth year, in those years when young men and young women contemplate marriage, when wives should be strong to rear their children, when husbands should be strong to maintain their homes, when we should be strong to do the world's work, in those most precious years tuberculosis has throughout the centuries been claiming every third or fourth of our race Consider how often the wage earner has first succumbed; and how, through the many months and the years of this chronic disease, his family must endure the privations imposed by it, and oftentimes in turn themselves become its victims. The world, moreover, has lost treasures immeasurable by reason of the untimely sacrifice of men and women of genius to tuberculosis, "death's direct door to most hard students, divines, physicians, philosophers, deep lovers, zealots in religion." Tuberculosis has ever been at least as great a devastating social and economic factor as it had been a death dealing infection, every year our nation alone has been sustaining by reason of it a monetary loss of more than a thousand millions of dollars.

Reflect upon all these things, and then turn the mind to the year of Koch's birth—1843 In that year Pasteur entered the university

And let us premise here that in science great names are landmarks, and the owners of these names have traversed and gleaned in the fields where many a devoted and now forgotten laborer has delved and sown and perhaps sweated blood It should indeed be a comfortable observation that in science at least no man works in vain Full many a one has given his whole life to establishing a fact, or indeed only an item to a fact, his industry unrecognized, ridicule and even persecution oftentimes his only compensation, living perhaps in the pitifulest destitution, yet his life and his works have been absolutely essential to the universal scheme There is the human unit, and there is the welfare and the very existence of the race, which latter were impossible without the self abnegating labors of the individual

Nor does it in any wise detract from the gratitude due the great man, that he had profited by the labors of others, adding what he can of his own, scrutinizing every detailed datum in the whole fabric permeating and illuminating it with his own mind, and extracting from the mass the mighty deductions of genius. Thus did Jenner's inoculations, upon the principle of fighting fire with fire, make clear the way for Davaine and Lister and Pasteur, upon whose substructure Koch built. These latter developed the germ theory of disease, Koch made of this theory the science of bacteriology, which is to-day the most potent factor in civilization. Pasteur declared it to be within human power to banish all parasitic diseases from the face of the earth, Koch clearly demonstrated how this business was to be gone about.

When Koch was seventeen he persuaded his father to get him a microscope Possessed of this most congenial companion, he set about perfecting other technical means of investigation For even genius cannot work effectively without good tools After attaining his doctorate in medicine he became a simple country doctor, utilizing the time which—mournful to relate—every beginner in practice has a plenty, in scientific study experimentation research, and writing In those years he laid all the foundation of his future greatness. At that time he was not enrolled in any world-famous institution, nor had he millions at his back Such aids to success are not to be decried, yet it is amazing how frequently genius, burning unquenchably in the service of humankind has managed to get along without them, how they never avail at all in the absence of the right man.

But soon the German government became cognizant of Koch's writings. That government recognizes good work; it avails itself of ability, it engaged Koch in its service

It 1882 came his truly epochal discovery of the tubercle bacillus, the essential cause of tuberculosis Here was laid down the sure and scientific basis of the anti tuberculosis propaganda which has since been so successfully waging Upon this foundation were preventive measures intelligently formulated and with wonderful result up to our day In Prussia (Koch's own country) the consumption mortality has been reduced forty per cent, in Boston, forty five per cent, in New York city fifty per cent In our northern cities twenty per cent in the years of 1901-6 And it is being confidently predicted on the basis of the prophylaxis thus far achieved that our children—yes, even we in this generation—may see this dreadful scourge of the centuries all but eliminated from human experience Koch elaborated various tuberculins diagnostic of tuberculosis, their curative properties have unfortunately proved disappointing yet they were the basis of the wonderfully effective antitoxins of diphtheria, tetanus (the most agonizing of all diseases of which formerly nearly all the sufferers died) meningitis pneumonia, and other dreadful infections

And Koch's achievements in tuberculosis were only a part of his service to mankind In 1883 he discovered the cholera bacillus which is responsible for that disease In the investigation of other world scourges—cancer bubonic plague septicæmia (blood poisoning), trypanosomiasis cattle plague, anthrax malaria—Koch's part has been most vital, either as discoverer or as originator or developer of prophylaxis and curative methods

He showed how malaria could be absolutely vanquished by stamping it out of the island of Brien in the Adriatic, under commission of the Austrian government In Bombay he studied the bubonic plague at first hand When long past threescore he repaired to a desolate island in Victoria, Nyanza his only white companion being an army surgeon and throughout the whole of eighteen months they together saw but three other whites A rough canoe, hewn out of a single log, was their only means of communication with the mainland There Koch discovered the crocodile's blood to form the chief nourishment of the tsetse fly, the blood-sucking insect that transfers the

DR. ROBERT KOCH

# The Collection and Preservation of Moths and Butterflies

BY FREDERICK M. SCHWERD

The most beautiful members of that very large zoological class termed insects are butterflies and moths. Because of their beauty they have always received more or less attention from collectors young and old. Many have started to gather these insects, but because of lack of the knowledge of how to preserve them their so-called collections have spoiled, and the specimens have become broken and moth-eaten. In the following words I shall endeavor to describe, without the use of scientific terms, a method in which to preserve their captures, and which gives such pleasing results that the finished labor will be a source of enjoyment both to the collector and his friends.

The specimens must be caught before being preserved; therefore, it will be most convenient to begin with a description of the primary requisite for this work.

The Net.—The frame or rim of the net is easily made from a piece of iron or telegraph wire about forty-two inches long. This wire is bent in the form of a loop, leaving two straight ends, each about four inches long, in the manner shown in the illustration 1. Some sort of rod must then be secured, to serve as a handle. A broom handle answers this purpose very well, but a rod about an inch in diameter and five feet long can be procured at any lumber yard for a few cents. Through this rod about half an inch from the top a hole is drilled, as shown in Fig. 2. The straight ends of the wire are pushed through this hole, one from either side. The projecting ends are fastened against the handle with staples or wire wound around. (See Figs. 3, 4, and 5.) Only the making of the bag remains. For this purpose tarletan or other fine netting of a brown or green color should be used. Mosquito netting is rather coarse and should not be used, as it scratches the wings of the insects. The bag should be about twenty inches deep and the bottom rounded as in Fig. 6. It may then be attached to the rim by means of tape.

How to Kill the Insect.—When the insect is fluttering in the net, the question arises how to kill it painlessly and quickly. This may be accomplished in several ways. Most collectors use a cyanide bottle, which is prepared in the following manner. Into a wide-mouthed glass are placed a few lumps of cyanide of potassium. Upon these is poured plaster of Paris to the depth of one inch. When the plaster is dry the bottle is tightly corked, and must not be left uncorked. The body of the insect is gently held between the thumb and index finger (7) and a drop of chloroform is dropped upon its head from a vial carried in the pocket. The insect immediately stops its fluttering and may then be taken from the net and placed

(Continued on page 490.)

Pushing pin through a specimen. 12. Bending wings into horizontal position. 13. Pinning insect to a board. 14. Insect between glass pieces before mounting. 15. Insect mount, showing glass shelf.

COLLECTION AND PRESERVATION OF MOTHS AND BUTTERFLIES.

# BERTILLON AND THE BURGLAR'S "JIMMY"

BY JACQUES BOYER

The police officer or magistrate engaged in the elucidation of a crime, endeavors to collect as many exact facts as possible and the more methodically he seeks verifies and gives a logical grouping to his evidence, the greater is his chance of discovering the true cause and the perpetrator of the crime.

M. Bertillon, the celebrated chief of the anthropometric service of the French police, has recently invented a dynamometer of special character, which will facilitate judicial investigations by furnishing exact measurements of the muscular efforts which are manifested in the violent entry into a house, room, or desk, and by making it possible to reproduce the traces of his work which the burglar has left on doors and articles of furniture. The apparatus consists of a steel frame, which is attached by screws to a wooden table. It contains a lower plate which can move forward and back, two lateral uprights stiffened by curved braces, and a cross piece of steel attached by strong bolts to the tops of these posts. This frame carries

# HANDY MAN'S WORKSHOP

## GAS WATER HEATER FOR KITCHEN BOILERS.

BY JOHN A. BERGSTROM.

One of the chief drawbacks of the gas kitchen range is the problem of maintaining a suitable hot water supply. A small heater attached to the kitchen boiler will overcome this trouble. The accompanying illustrations show how such a heater can easily be made and connected at a very small expense It will only take a few minutes to heat enough water for a bath or for washing dishes or clothes. As the hot water rises and stays at the top of the boiler until drawn off at the faucet it is not necessary to heat all the water in the boiler, as is the case when it is connected with the kitchen range in the usual way, but only such amount as may be required for the time being The heater as illustrated in the vertical section, Fig 2, and cross section, Fig. 3, consists of a copper coil, inclosed in a casing, with a gas burner in the center of the coil, and it is connected to the kitchen boiler at the top and bottom. The gas burner can be made with or without a primer or lighter It can also be connected with a self-lighter to be operated with a push button in the usual way

Take an ordinary tinned copper tube about one inch in diameter, and fill it with fine sand, closing the ends with stoppers. With a wooden mallet begin about 3 inches from each end to flatten the pipe, until it is ¼ inch in thickness. After this, make a wooden center, say 6 inches in diameter, with one end tapering or rather rounded off. One end of the tube is now fastened to this wooden center and the flat pipe is wound around the same, forming a close helix. The other end is then formed over the tapering end of the wooden center by hammering it into place with the mallet, until the coils begin to close up, leaving enough space for the spent gases to pass out The end must of course be made straight and in the center so that it will enter the central hole in the casing or cover which is to be connected to the boiler

After the coil is made into the required shape, the stoppers in the ends are removed, and the sand made to run out by turning the coil around and tapping it lightly with the mallet. It may then be connected to a faucet and washed out with water The lower end of the coil may be bent at any angle to suit local conditions

The externally threaded end of an ordinary ¾-inch union is now slipped over the end of the coil which is peened over, say about 3/16 inch, forming a flange which serves to connect the copper tube and iron pipe with the ordinary union. (See Fig. 4). This should be done at each end of the coil. Of course the heads of the casing should be put on before the unions are fastened to the coil. The coil is now inclosed in a sheet iron casing (a piece of 6-inch stove pipe) with a layer of asbestos between the coil and casing.

The top of the casing is connected to the chimney or the atmosphere with a small pipe, to carry off the burnt gases. If connected with the outside atmosphere, a suitable cap or hood should be provided at the outer end so that the wind will not blow through it and extinguish the fire.

The burner is made out of an ordinary nipple, with caps on each end. In the nipple are drilled a number of small holes. Inside the nipple is a small iron cylinder with conical bottom, and provided with a small flange at its upper end, where it is fastened between the end of the nipple and the cap The object of this cylinder is to partly fill up the inside of the nipple, leaving a small annular space for the gas and air to pass up and out through the small holes in the nipple. To the lower head of the casing is fastened an ordinary air regulator, into which the gas pipe is secured, forming an ordinary Bunsen burner

The main feature of this heater is to introduce the water in a very thin, circular sheet surrounding the central heater It will now be seen that when the gas is lighted the water in the flat coil becomes hot and starts to circulate around the fire up the spiral course to the top of the boiler The temperature of the water may be regulated by inserting a valve below the coil, but for ordinary use this is not necessary

Fig 1 shows the complete heater connected up to a kitchen boiler with a vent pipe for the spent gases connected to the chimney

Fig. 5 shows how the heater may be fitted up with a primer, or starter for the gas, which is merely a small independent Bunsen burner, connected below the regular mixing tube This burner is first lighted, the flame will shoot up into the heater, the ordinary gas-cock is then turned on and the gas ignited, when the primer may be turned off. This is only a matter of convenience in starting the big burner, as a match or a taper will do the same thing

Fig 6 shows a system in which the heater proper is located in the basement and the supply pipe, instead of being connected to the boiler or storage tank, is controlled independently from each floor The heater is equipped with an electric self-lighting apparatus, such as may be purchased in the market. An ordinary "off and on" push button is placed at each floor, near, or it may be connected to the water faucet. The apparatus is quite simple, it is only necessary to push a button, which will ignite the gas in the heater, and then open the faucet. The cold water in the pipe will run out, of course, before the hot water makes its appearance The temperature of the water can be regulated by the faucet. That is to say, the greater the heat desired, the smaller should be the quantity allowed to run through the faucet, and vice versa When no more hot water is wanted the other button is pushed, which cuts off the gas and puts out the fire in the heater, and the faucet is closed This operation may be repeated any time hot water is wanted. If cold water is wanted, it is only necessary to turn on the faucet, without starting the fire Thus hot or cold water may be drawn from the same faucet at will.

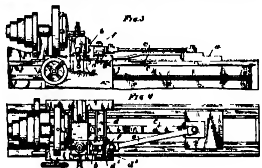
SIDE AND PLAN VIEWS OF RIG FOR CUTTING A CONCAVE SURFACE.

## TURNING CONCAVE AND CONVEX SURFACES.

BY E. B. UTTERHARDT

Some time ago the writer had occasion to make a pair of laps for grinding telescope lenses, and as this calls for very accurate work in order to get a true curve, it became necessary to make the attachments which are here described In this class of work it is imperative that the utmost care be given the construction of the several parts, as upon the accuracy of the measurements and nicety of fit depend the quality of the finished product There must be no lost motion anywhere, as this would mean chatter marks on the surface of the work. For this reason it is better to use taper pins or bolts as these will insure a close fitting joint, and the extra trouble will be more than repaid The rigidity of the radius bar is of vital importance, it is far better to have it too heavy than too light. Nothing is better than a good cast iron bar, for it is less apt to spring than steel For radii of 15 to 24 inches, a bar ⅝ by 1½ inch cross-section is none too heavy, while for radii of 24 to 36 inches ¾ by 2 inches is of about the proper proportion



LATHE RIGGED TO TURN A CONVEX SURFACE

Figs 1 and 2 show front and plan views respectively of the concave attachment The radius block *a* is bored to make a close fit on the nose of the tail-stock spindle, and is provided with a tightening screw *b* for binding the block securely in place It will be observed that the block is split where the tightening screw works The lugs or ears which receive the radius bar *c* are now finished on the inside, and the holes for the pin or bolt *d* are drilled Care should be used to get these holes directly in line with the dead center, it may appear that a slight variation one way or the other may be of no account, but it is A good mechanic always adheres to the rule "Anything worth doing at all is worth doing well The block *C* is secured in any suitable manner to the tool post slide As this part of various makes of lathes differs it is impossible to give a form of block to fit all but any good mechanic can devise means for securing one to his lathe Regarding the radius bar *c* little can be said except the spacing of the holes On the accuracy of this depends wholly the accuracy of the curve of the part machined Fig 2 shows the tool on a line with the center, in which position it is set before starting to cut. The tail stock is now clamped in position, while the lathe carriage should be free to move back and forth on the ways As the tool post slide is drawn toward the operator the carriage will be drawn back, causing the cutting tool to describe an arc the radius of which is equal to the distance between the centers of the holes in the radius bar The tool is fed to the work by turning the hand wheel of the tail stock screw while the cross feed is accomplished in the usual manner

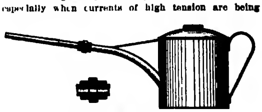
Figs 3 and 4 represent the device for turning convex surfaces, which is somewhat more complicated than the mechanism described above The radius bar used for concave work can be used here but all of the other parts must be made especially for the purpose The block *a* must be planed and fitted to the inner ways of the lathe and mounted in such a manner that it can move freely backward and forward The slide *d* which carries the cross-slide block *d'* is securely bolted to the lathe bed Bolted to the sliding block *d'* is the bearing *d''* to which is secured the forward end of radius bar *c* On the upper side of block *d'* is a roller which runs in the slot in block *b* the latter being secured to the tool post carriage The lathe carriage and block *a* are rigidly connected by means of the bar *c*, the front end of which may be bolted to the bridge webs as shown by the dotted lines. The operation is as follows, bearing in mind that slide *d* is rigidly secured to the bed As the tool post slide or cross slide is fed forward, the sliding block *d'* is carried with it by means of the slotted block *b* and roller *f* As sliding block *d'* advances carrying with it the forward end of radius bar *c*, it becomes apparent that block *a* must move backward, and as this block and lathe carriage are rigidly connected by bar *c* the lathe carriage will be carried with it, the result being that the tool is caused to move in a reversed arc. It might be well

to state that in order to avoid resetting, it is a good plan to have the blank which is to be machined cast with a convex face of about the same curve as it should be when finished. If this is not done or we wish to use flat disks of cold-rolled steel or other metal, it will be necessary to move the cutting tool forward after each cut.

### A SAFETY OIL CAN

BY A. J. JARMAN

When oiling electrical machinery, it is always advisable to safeguard yourself against accidental shock, especially when currents of high tension are being



OIL CAN WITH INSULATED TIP

generated. It frequently happens when an ordinary long-spout can is employed for oiling dynamos that a severe shock is received by the oiler, resulting sometimes in death. Several years ago the writer invented an oil can that was perfectly safe under all ordinary conditions of use. Owing to the extreme simplicity of the design any one possessing ordinary mechanical ability can convert an ordinary oiler, either of the vertical or horizontal kind, into a safety oiler. Cut the spout in the middle and solder upon each end a piece of brass tubing having either an external or internal thread cut. Fit thereon a coupling sleeve made of insulating material as shown in the sectional view. The insulator can be made out of either hard rubber or vulcanized fiber turned in the lathe, with a milled center to admit of a firm grip when screwing or unscrewing the parts. Since oil is an insulator, no current can get past the coupling sleeve to the oiler's hand.

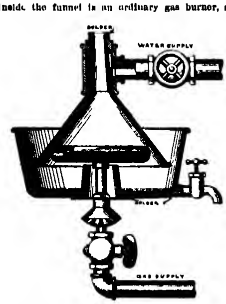
### INSTANTANEOUS WATER HEATER.

BY GEORGE M. PAUL

The old proverb, "A watched kettle never boils," does not apply to the water heater shown in the accompanying illustration because hot or even boiling water can be drawn from it the instant it is put into operation. It is made from an ordinary copper funnel and a cake tin.

The copper funnel should preferably be tinned on the outside. To the water supply pipe is attached a valve for the regulation of the flow of water. To this valve is fitted a short nipple and an ordinary tee fitting. One end of the arm of the tee is fitted with an ordinary plug which is bored and reamed out to fit the small end of the funnel and the end of same is turned over with a small hammer and soldered to the plug. The other end of the tee is filed to fit very closely to the outside of the funnel, leaving, however, a slight annular opening which may be regulated by screwing the plug in or out, so that when the water is turned on it will flow in an even thin sheet over the funnel.

Inside the funnel is an ordinary gas burner, such



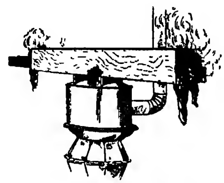
HOME-MADE INSTANTANEOUS WATER HEATER.

as may be purchased for ten cents. This burner is connected to the gas supply in the usual manner. It will be noticed by referring to the illustration that the funnel is in an inverted position. The lower part of the funnel is surrounded by an ordinary cake mold, with the inside cone partly cut off. This tin forms a basin for the hot water which may be drawn off with an ordinary faucet soldered to the cake tin, or it may be run off as the water heats. It will now be seen that when the gas is lighted the funnel becomes hot at once, and when the water is turned on it is forced through the narrow opening between the tee and the funnel in a uniform thin sheet which spreads over the funnel and becomes hot as it flows down. Almost any degree of heat may be obtained by regulating the flow of water with the valve. The spent gases from the gas burner pass up through the funnel and out to the atmosphere. Some arrangement may be made to connect the water and gas valves so that they will be turned on simultaneously, thus obviating the danger of overheating the funnel.

### STEAM BOXES FOR BOAT BUILDING.

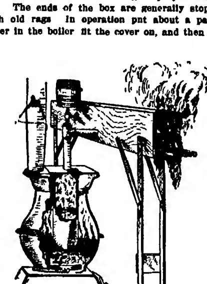
BY A. F. BISHOP

A simple method of rigging a steam box for boat work is as follows: Take a common wash boiler, put a 1¼ inch hole in the cover to receive a short piece of tubing 2 or 3 inches long, which should be soldered. The steam box is made of wood, of any length desired, and about 10 inches high by 8 inches wide inside. Make a couple of chocks hollowed out to fit the top of boiler cover, and nail them to the box. Cut a round



STEAM BOX CONNECTED TO A WASH BOILER.

hole in the bottom of the box to receive the tubing that has been placed in the cover of the boiler. Be careful not to allow the tubing to project inside the box. The ends of the box are generally stopped up with old rags. In operation put about a pailful of water in the boiler, fit the cover on, and then lift the



STEAM BOX CONNECTED TO A CAST-IRON MUFFLER.

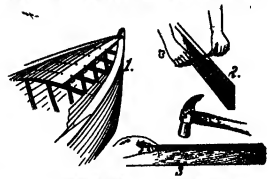
steam box and place it on top of the cover, allowing the tubing to enter the bottom of the box.

Another method of constructing a steam box has been devised by William Ellis, a boat builder. It is made by taking a cast iron muffler, plugging the lower end, and connecting a short length of 1¼ inch pipe to the opposite end. A tee is put on the end of the pipe with a short piece of 1¼ inch pipe screwed into the tee at right angles to the muffler piece. The upper end of the tee is plugged up with a wooden plug, if there is no reducer handy.

Bore a hole in the wooden plug, and screw into it a short piece of ¼ inch pipe, fitted with a stop cock of some sort. Above the stop cock, place a can or wooden paint pail, which is quite easily attached by simply boring a hole in the bottom and screwing to the short nipple above the stop cock. In operation, the muffler is placed in the stove with a coal or wood fire. A piece of sheet iron with a hole through which the pipe projects, serves as a cover for the stove. Water is poured into the paint pail and allowed to run down into the muffler as desired. A wooden steam box mounted on legs is connected to the muffler by the 1¼ inch pipe. This style of boiler is not injured if it boils dry, and is frequently red hot when the water is put in. This, of course, makes it "flashy," but otherwise no harm is done, as the pipe is of sufficient size to handle all the steam that is generated.

### MAKING TIGHT JOINTS IN BOAT DECKS.

A boat deck is more exposed to severe attacks of the elements than any other part of the boat. The hot sunshine may be drying it up half the time, while during the other half, it may be covered with rain, dew, or salt water. And on this account the majority of boat builders calk the seams, which does not make



MAKING TIGHT JOINTS IN BOAT DECKS.

as pretty a deck as a tight seam, made in the following manner.

Have the wood thoroughly seasoned and make a nice fitting joint for the deck plank that you are laying next to the plank sheer. When this is done, take the piece out and with a smooth steel rod or burnisher of some kind, burnish down, with quite a pressure, the corner of the jointed edge, as in Fig. 2 of the accompanying drawing. This of course compresses the wood. Now plane the wood down on the jointed edge, making a true corner again. This is now ready to fasten on the deck carlins. Proceed in like manner with the rest of the deck planks. The joints on a wooden tank or vat can be made tight by the same principle. Instead of burnishing the corner a round rod is laid in the center of the jointed piece and with a hammer is forced nearly half its diameter in the wood. (See Fig. 3.) This is planed down until there is no groove left, each joint is treated in the same way. When the wood is moistened, the part that has been compressed by the round rod will expand. This produces a very tight joint.

### TO PREVENT OBSTRUCTION OF THE FEED PIPE IN AUTOMOBILES.

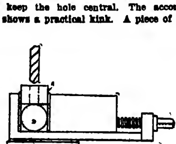
BY F. J. WATSON

Among the worst and most costly troubles of the amateur motorist are those connected with the piston, and if he is unable to discover the cause of the disorder he may have to pay heavily for curing that which could be avoided by observing the following simple precaution.

Recently when my engine failed to work properly I determined to look into the matter myself, and started by removing the cylinder heads. I discovered small particles of metal around the edge of the cylinders and the cylinders themselves were scratched up. Tracing this to its cause I discovered that the feed pipe was almost clogged up with small particles of corroded copper. Going further, my gasoline tank showed signs of corrosion which I attribute to poor gasoline, containing considerable moisture thereby causing corrosion of the copper tank. After giving my tank a thorough washing and scraping I had it electroplated inside with a coating of tin. All particles of metal were removed from the cylinders, the feed pipe was cleaned out, and the parts were connected up. I have been running my motor for the past eight months without the trouble recurring, and have saved myself the cost of a new tank.

### HOW TO DRILL A HOLE CENTRAL IN A BAR.

It is a rather difficult matter to drill a hole in a bar and keep the hole central. The accompanying drawing shows a practical kink. A piece of tool steel



METHOD OF DRILLING A HOLE CENTRAL IN A BAR.

*A* is caught in the lathe chuck, and is turned and bored so the hole will run true with the outside diameter. The outside diameter is turned the exact size of bar *B*, which is to be drilled. The bar *B* is placed in a vise as shown, the drill jig *A* is placed on top of the job, and the vise is then tightened up. As the jig and the bar are of the same diameter, the vise will hold them both very rigidly while the bar is being bored.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

BRAIDED NECKTIE.—O. Holbert and O. Thoernaus, New York, N. Y. This tie is so braided that the neck-band portion will be substantially inelastic and of a close weave, permitting it to slide easily between the folds of a turn-down collar The tying ends are formed integral with the neck-band and are of greater width and looser weave than the neck-band portion and the terminal portion of each tying end is of tubular form and turned back, so that the free edges are concealed within the bulb There are the same number of threads the entire length, and means provide for ornamental design.

### Electrical Devices.

BRACKET FOR TELEPHONE-RECEIVERS.—H P Voss, New York, N Y The object of the inventor is to provide an attachment for a telephone of the class which refers more particularly to desk telephones, which will enable the receiver to be adjusted to the ear so that it will be supported in the proper position, while leaving both of the hands free to write or to make memoranda of the conversation.

DENTAL FORCEPS.—E. C Lombard New York N Y The forceps are of that type commonly employed for the extraction of teeth, and the object of the invention is to so construct the forceps that a current of electricity may pass from one jaw of the forceps through the tooth or the gum to the other jaw of the forceps while the forceps are in use

### Of General Interest.

FENCE-POST AND ANCHORAGE BASE.—P T Bailey Newport, R I An object of this improvement is to provide a base which may be made of thin cast metal or constructed from compressed sheet metal, the purpose being to provide a strong, light construction which may be cheaply manufactured The various forms of blades and spikes together with the post, may be formed of thin castings of rolled sheet metal which can be pressed into the desired shape

MUSICAL INSTRUMENT.—W H Dressenau Haselhurst, Wis. The invention refers to gramophones. Means provide for connecting the stylus with the bridge of the violin and for supporting a violin on the casing of the gramophone A stylus or needle is attached to a violin or a like instrument, and the latter is held suspended with the stylus in contact with a revolving record, so that the violin forms the sound reproducer and amplifier

CONCRETE WALL CONSTRUCTION.—L. Laperrounerie, New York, N Y The aim in this case is to provide a concrete wall construction arranged to provide suitable furring strips for fastening door frames, base boards, picture moldings and the like securely in place on the wall the said strips forming integral parts of the blocks of concrete or other plastic material

SAFETY GUARD OR SUPPORT.—L. B Mullica New York, N Y The invention pertains to guards for watches and the like, and the object is to provide a guard or support which is simple and durable in construction exceedingly strong and arranged to hold an article such as a watch, garment or the like securely in position and against accidental detachment or forcible removal by unauthorized persons.

TOOTH-CROWN.—P Schaefer, Oakland, Cal This invention relates to certain improvements in tooth crowns, and more particularly to certain improvements in the manufacture of the pattern or model in imitation of which the gold crown is cast The tooth crown conforms perfectly to the tooth as an annular band for fitting around the tooth presents the desired contour and is all formed of a single casting.

### Hardware and Tools.

BANK NOTE CUTTER.—H E. Horn, Hanover, Pa The purpose of this inventor is to provide a cutter with a plurality of blades, which will hold a sheet of notes in position to be cut when the handle is operated, the frame of the cutter being open so that the notes fall therethrough when cutting.

CIRCULAR-GLASS CUTTER.—W Chase, Jr., Indianapolis, Ind. Among the principal objects which this invention has in view are the provision of an implement which may be centrally located upon the surface of glass and there immovably held, and to provide a swinging arm pivotally mounted upon a fixed structure and hingedly secured thereto.

STAPLE.—H F Merrill, Williston, N D Among the principal objects of this improvement are to provide a device having two anchoring extensions adapted to be driven into wood to form the grooves extended laterally from the path of the insertion of this device, and to produce a fastening device which is economical in structure, and durable and efficient in operation.

WINDOW-BLIND HOLDER.—O. Thomasek, New York, N. Y. This invention relates to mechanism for use in holding blinds and analogous structures, the more particular purpose being to enable the operator to secure the blind rigidly in an infinite number of definite positions, so that the screening effect of the blind may be more readily controllable at will.

### Heating and Lighting.

VAPOR BURNER.—A H. Waite, El Paso, Ill. This invention is an improvement in vapor burners of the character disclosed in Letters Patent formerly granted to Mr Waite. The principal features are pipes which curve about at opposite sides of the perforated top of the evaporating burner and directly above the screen of this burner, each pipe having an open forward end turned downwardly at the front of the stove These at their opposite ends are connected to a common pipe, which passes through an air duct, and discharges at the vaporizer

HYDROCARBON BURNER.—B L. Wortmen, Tucson, Ariz. The improvement is adapted to various purposes of the arts and one of the principal objects thereof is to provide a hydrocarbon burner in which crude oil associated or combined with air, steam or other aeriform fluid, is most economically and effectively utilized in the production of a flame developing the maximum of units of heat and of force possessing the maximum of intensity

MOP-WRINGER.—S T Atkin Georgetown, Texas. This invention is an improvement in mop wringing devices for use on buckets or pails. The mop wringing attachment is designed for use with that class of mops wherein the ends of the mops are held in the holder and the mop is formed into a looped form which may be fitted over the wringing arm and then twisted to wring out the water The wringing arm is located within the bucket, reducing the liability of overturning the bucket during the operation of wringing the mop

### Machines and Mechanical Devices.

DEVICE FOR AUTOMATICALLY DELIVERING ARTICLES.—N R Stiles 34 Leadenhall Street London E C, England This invention relates to devices for delivering articles automatically from a container and is specially applicable for the delivery of cigarettes and the like from a cigarette container Devices of this character as hitherto proposed have been unreliable in practice usually on account of the faulty feeding means to the element which selects the articles to be presented

BRICK MOLDING MACHINE.—T Young Lakeland Fla The object of the inventor is to provide a machine in which the bricks may be molded, in which the bricks are readily accessible, and which will separate from the bricks with the least danger of breaking and crumbling It relates to brick molding machines in which the material is forced into the mold by tamping the bricks being then removed to be dried and baked

ROTARY FAN OR PROPELLER.—H Rothenberg 52 Königs Allee, Villen Colonie Grunewald, Berlin Germany The invention relates to improvements in rotary fans or propellers adapted to act upon the air and particularly to such air propellers as are used for propelling air ships or flying machines and which are actuated either by hand or mechanical means.

### Prime Movers and Their Accessories.

GAS ENGINE VALVE TIMER.—T P Hirnax North Bend Ore In operation the engine which is preferably provided with a compressed air starting device and with the usual sparking device is started by the said compressed air device To reverse the engine it is necessary to move the lever to the neutral position before it can be reversed Means provide for operating the valve to open the exhaust at every revolution of the crank this being necessary for the proper working of the engine when starting

### Railways and Their Accessories.

STATION INDICATOR.—C Messinn New York N Y This invention pertains to a new and improved device to be used in street cars railroad cars subway trains and the like to indicate the various stations, stopping places or streets. An object is to provide a station indicator which may be used on any number of branch lines with means for changing from one branch to another such means including prevention of overrunning the changing point.

### Pertaining to Recreation.

GAME APPARATUS.—W A Sullivan New York, N Y This invention relates to a game apparatus, and has for its object to provide an apparatus having a member supporting a ball which is adapted to be moved laterly by a baseball bat in the hands of a player, there being means which is adapted to indicate the force of the blow as the bat is brought suddenly into contact with the ball.

### Pertaining to Vehicles.

TIRE-CASE.—C A Russell, New York, N Y. This improvement pertains to tire cases or covers such as used for enveloping automobile tires, or the tires of similar vehicles so that they will be protected from the weather Such covers are used especially on extra or spare tires which are carried usually in an exposed position somewhere about the body of the vehicle.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending May 31, 1910,**

AND EACH BEARING THAT DATE

THE MUSEUM AT MONACO.

(*Concluded from page 476.*)

left contain everything relating to physical oceanography, that is, the physical investigation of the sea, comprising all kinds of instruments, such as sounding devices with samples of the sea bottom, bottles intended for taking water samples and recording the temperature at a given depth, apparatus for investigating sea currents and the density of sea water, instruments for studying the penetration of light into the depth of the ocean, laboratory installations for the physical and chemical analysis of sea water and sediments, a collection of elements contained in sea water, etc.

All these variegated exhibits have been provided with labels in the three principal languages (French, English, and German) which greatly add to their utility and enhance their international character.

The first story, which is situated at 64 meters above the sea, likewise contains a large hall, in the center of which is exhibited one of the Prince's whaleboats with the whole of its equipment. On the walls are arranged six comprehensive collections of photographs relating to the voyages of discovery organized by the Prince, and all kinds of other oceanographic subjects. To the right of the entrance door is located a switchboard for the electric lighting. The two halls adjoining the central hall are likewise taken up by glass cases containing a large variety of exhibits. The eastern hall, which is eventually to contain everything connected with the chemical and physical investigation of the ocean, and part of the sounding and fishing instruments, is taken up provisionally by divers subjects, especially those connected with marine industries, such as the sponge industry—represented by specimens of different stages of manufacture and different origins (especially Tunis)—the industry of coral (in the shape of raw materials and finished products of different origins, especially Japan), as well as the industries of [illegible], shells, pearls, salt, [illegible] oil and skins, [illegible]. All the [illegible] supplied by the sea are on exhibit either in a fresh condition or as preserve; and even such materials as fish oil, guano meal, etc., are represented

Another subject of great interest, and which will have to be further developed, comprises all kinds of fishing instruments (boats, nets, etc ), either in the natural size or in the shape of diminutive models Many scientists and the Prince himself have designed special mechanical catching outfits for deep-sea fishing, while other instruments had to be constructed for gathering the microscopical plankton of the surface, intermediary zones and sea bottom, as well as for catching ocean animals of especially large size. All these manifold utensils are indispensable for obtaining an adequate knowledge of the customs, life, and evolution of those mysterious animals, and apart from their scientific interest, are of much practical utility by enabling suitable means of protection to be ascertained in the case of organisms lending themselves for industrial utilization.

In the same hall is found a representative collection of art subjects, imitating the wonderful and most variegated forms of marine organisms. Besides the most modern productions in this connection are represented ancient Greek models with pictures of fishes, crabs, and dolphins as well as Japanese engravings, which show an admirable treatment of fishes.

The two underground or basement stories opening on the sea are admirably lighted, and apart from the aquarium hall, are not accessible to the public, being set apart for laboratory and research work. The upper basement story contains those rooms in which the collections are made ready for exhibition and study, in addition to a number of private laboratories, and a special library intended for the benefit of students in oceanography.

Every laboratory contains fresh-water and sea-water conduits, and a special experimental table designed by Dr. J Richard, Director of the Museum, and where the animals under test can be kept alive for any length of time. Two of these private laboratories are especially equipped for researches relating to chemistry, ocean physics, physiology, etc., whereas the four remaining are set apart for zoological, botanical, histological, etc., investigations A large photographical laboratory is installed at the eastern end of this story

In the lower basement story is found a workshop destined for different kinds of rough work, especially the mounting of big animals, such as large fishes, whales, seals, etc The numerous apparatus installed therein are operated by a gas motor A special room is reserved for the dressing of fish and whale skeletons

Two rows of aquaria are installed in the eastern wing of this underground story An enormous iron-concrete table 21 40 meters in length, and 0 87 meter in width, parallel to the first row of aquaria (between the latter and the windows) is destined to receive a large number of transportable aquarium tanks of various sizes, the overflow from which is discharged direct on the table, the latter being so inclined that the whole of the water is collected in a central trough These excellently lighted research aquaria will allow of a multitude of physical and biological researches in the field of oceanography In the small aquarium basins can be investigated those smaller size animals which, being lost in the large aquaria, have to be conveniently isolated in conditions corresponding to their particular mode of life.

The sea water, derived from a rocky spot where owing to the continual whirlpool it is always fresh and well aerated, is thrown by two electric pumps to 64 meters height. From the receiving tank the water is supplied over a fall of several meters to the aquaria, allowing these tanks to be automatically aerated

The Oceanographic Museum thus is not only an institute intended for the instruction of the general public, but a center of scientific investigation where students of oceanography will always be sure to find an equipment more comprehensive than anywhere else in the world

The Seine at Paris runs between two stone walls in a channel that is spanned by many bridges. The width of this channel may be seen by noting that the largest and finest of these bridges—the

Pont Alexandre Trois—is but 352 feet long. The constriction of the flood waters within this relatively narrow channel was impossible, so it overflowed a large area along the banks of the Seine.

## DR. ROBERT KOCH.

(Concluded from page 488.)

trypanosomes which are the specific cause of the sleeping sickness, and there Koch elaborated most important prophylactic and curative measures against this most melancholy disease.

This faithful servant of his race never rested. Coming from Africa, he took part in the International Congress at Washington, observing then "I wish to devote myself for several years to come, to further investigations of these problems"—and this in his sixty-fifth year.

Thus Koch's sojourn among us means this. Formerly men folded their hands supinely in the presence of horrible infections, now we know that by means extraordinarily simple and practical (how amazingly simple, *after they have been evolved*, are the conclusions of genius), by the rational use of our faculties, and by realizing that we ourselves are coefficients in the working out of our own destinies, it is indeed within our power to be rid of those infections which have up to our time prematurely destroyed half our race.

## THE COLLECTION OF BUTTERFLIES.

(Continued from page 484.)

in the cyanide bottle, where it will quickly die (9). However, care must be taken in all these operations not to bruise the wings of the butterfly or moth. There are serious objections to this mode because the cyanide is poisonous, and even the fumes, if inhaled will prove dangerous. Although this method may yield good results to some collectors, I have always used a simpler and more effective way. A bottle with a medicine dropper as a cork is filled with benzine or gasoline (8). The insect is secured in the same manner as previously explained, and a generous dose of benzine is administered, which kills instantly. The benzine will spread over the whole specimen, but soon evaporates and leaves the insect none the worse for the bath. When the insect is dead, it is placed in a paper envelope made in the manner shown in 10.

Some of the large moths have greasy bodies, and will, therefore, have to be degreased. This may be done by placing the envelopes containing the insects in gasoline for twenty-four hours or more.

Spreading the Insects.—If on reaching home there is time to spread the insects caught during the day they should be taken out of the papers and treated in the following way. For use in spreading, a perfectly flat board with an absolutely smooth surface, some insect pins, some pieces of plate glass of different sizes, and a few needles stuck into match sticks are needed. The insect is taken between the thumb and the index finger, and an insect pin is pushed through the thorax, as demonstrated in 11. With a broad-tipped tweezers, which may be purchased at any instrument maker's for a small sum the wings are taken hold of where they join the body, and are gently bent open until they remain in a horizontal position. Then the insect is placed upon the board and the pin is pushed in. Now a pin is inserted behind the heavy vein, and the wing is gently drawn forward until its base is perpendicular to the body. The pin is pushed into the wood. This operation is repeated with the other wings, and strips of glass are placed on them to press them flat. The pin which was first thrust through the thorax is now gently extracted. While the pin is being withdrawn, the pieces of glass should be held with the thumb and the first finger of one hand. The insects are left on this board for a week or two, and may then be removed for mounting (14). If the insects have

(Concluded on page 491.)

(Concluded from page 490.)

been left for any length of time in the triangular papers, they must first be relaxed or softened. This may be done by placing them over night between moist cloths in a box, adding a few drops of carbolic acid to prevent mildew They should then be spread in the manner previously explained.

Mounting.—The last step in the preservation of the insects is the mounting There are various ways in which this may be done, but the writer knows of none better than that invented by Denton Brothers of Wellesley, Mass Cases of glass are made, varying in size with the size of the insect to be inclosed These cases permit of a clear view of both the upper and under side of the specimen, as the top and bottom are made of glass. The insect is supported by its wings on a glass shelf (15) When the insect is placed in position, the top which is hinged at one edge is closed over it and is sealed with the passe-partout binding which forms the sides of the box So simple is this method of mounting, that even a child can obtain very fine results The mounts can be obtained at prices ranging from five cents up There is another mount with which good results can be obtained—the Riker insect mount. These mounts consist of a neat cardboard box having a glass top cover and filled with fine cotton batting, in which the insect is readily embedded The glass cover when closed holds the insect in place The only objection to these mounts is that both sides of the insect are not visible, and therefore two specimens will have to be mounted to show both the upper and under sides. Riker mounts may be obtained from all instrument makers having a natural history department

Collection of Specimens.—Now that the method of mounting and preserving the insects is known, the next thing to be done is the collecting of specimens But terflies may be found in the open fields which are covered with wild flowers or in the sunny openings in the woods Here the collector must stalk them Never run after a butterfly You probably will not catch it and moreover may scare others resting near As soon as the butterfly alights upon a flower, approach it carefully until within about five feet, then with a rapid sweep of the net capture it The moths are harder to find because they fly at night The method most often resorted to by collectors is known as sugaring A mixture of brown sugar, stale beer and molasses is made, and at dusk is painted upon the trees. In a few hours, if the locality is productive the moths will be hovering about the trees in abundance, keeping the collector busy half the night.

Naming and Classifying.—When the insects are mounted they will have to be named and classified Butterflies and moths belong to the order called *Lepidoptera* Few people know the difference between butterflies and moths There are several great differences In the first place, all butterflies have club-shaped antennæ or feelers, that is, the feelers terminate in a club All members of the order Lepidoptera which have not club-shaped antennæ are moths In the second place, all butterflies are diurnal that is, they fly by day, while most of the moths are nocturnal or fly by night Several minor differences may be noted, the first of which is, that butterflies generally hold their wings erect when at rest, whereas most of the moths fold them down Secondly, butterflies transform from the caterpillar stage to the winged stage in a naked chrysalis, and moths have a covering, no matter how primitive, which is called a cocoon.

Reference Work.—In all entomological work standard books are necessary in order to identify the specimens. Dr Holland's Butterfly book and his Moth are standard American works, and in them may be found colored plates comprising pictures of most of the butterflies and moths of North America, north of Mexico, with pictures of their caterpillars, chrysalids, and cocoons

### BERTILLON AND THE BURGLAR'S JIMMY.

(Concluded from page 481.)

two dynamometers of unequal power The stronger dynamometer having a maximum capacity of one ton and designed for the measurement of vertical efforts is connected to the top of the frame by a screw, by means of which it can be raised or lowered a few inches The lower spring of the dynamometer is attached to a heavy vertical steel plate, which slides in grooves along the two vertical posts When the index of the dynamometer is at the zero point, the bottom of this plate which is about 1½ inches thick, is about ¾ inch above the sliding horizontal plate In this interval is inserted a wooden board ¾ inch thick, with its edge flush with the bottom of the vertical steel plate The experiment is made by inserting between the board and the vertical steel plate the end of a "jimmy" or other burglar's tool and endeavoring by moving the handle of the tool up and down, to produce on the board impressions similar to those which have been found on doors and furniture The index of the dynamometer moves in accordance with the effort exerted and by means of a second index which remains fixed when the first returns to the zero mark the instrument automatically registers the effort required to produce a given impression

The figure thus obtained indicates only the vertical effort or effort of pressure but there is always a horizontal component of greater or less magnitude and this is registered by a horizontal or traction dynamometer, which is attached to the sliding horizontal steel plate

Either of the dynamometers can be used alone or both can be employed simultaneously In this way it is possible to measure the horizontal and the vertical efforts separately or in combination In the latter case M Bertillon has found that, as might be expected the horizontal effort is always much smaller than the vertical or pressure effort For example, using a lever 20 inches long a vertical pressure of 1 300 pounds was obtained simultaneously with a horizontal traction of 330 pounds A strong man, operating on a hard walnut plank can develop a pressure effort of 1 500 pounds

The apparatus can also be turned over on its side so as to place the experimental board in a vertical position for the purpose of investigating the forcing open of a door In this case a second piece of wood is introduced to represent the jamb of the door The same arrangement in the normal position of the apparatus, is used for investigating the opening of a drawer or a cylinder or other desk etc

The idea of employing a dynamometer in the study of burglary appears so simple, that it is surprising that it was not done long ago Henceforth judicial inquiries will be guided by the results of a series of experiments which will furnish points of reference From measurements made with the Bertillon dynamometer it is possible to discover whether the burglarious entrance was effected by a man, a woman a child or several persons

Finally the study of the impressions made by tools has led M Bertillon to give these impressions distinct names according to the part of the tool by which they are produced The word "foulée" is reserved for the impression made by the point of the tool "échancrure" for the notch made by the body of the tool in pressing on the edge of a door or piece of furniture, and the word "pesée for the indentation produced by the elbow of a "jimmy or similar tool on a plane surface For the identification of the tool the most valuable evidence is furnished by the "foulée"

## A STEEL ARCH SUGGESTED FOR THE QUEBEC BRIDGE

AT the time when the plans for the 3,100-foot Hudson River bridge were under discussion and it was generally accepted that the only type of structure that would lend itself to the then unprecedented span of 3,100 feet was either the cantilever or the suspension bridge, there appeared a remarkable paper by the well known bridge engineer Max am Endo, in which a design was presented for a steel arch bridge of 3,000 foot span, which was to be erected on the cantilever principle, the load, during erection, being carried by tying it back to suitable shore anchorages until the final keystone was in place In a recent issue of Engineering News, a similar proposition is made by Charles Worthington, for the construction of an 1,800-foot steel arch at the Quebec Bridge crossing The elevation of the bridge shows the characteristic beauty of the stee[illegible] Mr Worthington is convinced as the result [illegible] study of the problem, that not only would [illegible] of this magnitude be practicable, but that in [illegible] cost it would compare favorably with a brid[illegible] on the cantilever or the suspension princi[illegible]vided, of course that suitable abutments could [illegible]vided to take the enormous horizontal com[illegible] the thrust. This it is proposed to do by con[illegible] a huge concrete strut, or compression member [illegible] ground, extending from the base of the piers to [illegible] rock of the river bluffs Each strut is 20 f[illegible] and 98 feet in width, and should therefore [illegible] sufficient for its purpose

Certainly, the most difficult problem is that of [illegible]tion, and Mr Worthington proposes to solve [illegible] the original method of building an erection [illegible]sion bridge entirely across the site, and susp[illegible] the individual voussoirs, of which the main [illegible] is composed, from the cables, the lower ends of the latter being provided with adjustment devices by which the voussoirs can be held in proper position during erection The abutting faces of the voussoirs would be accurately machined and provided with flanges by which each section after it was lowered into position would be secured to the erected portion of the arch The arch consists of four parallel ribs of hollow rectangular section, each 21 feet deep at the crown, 43 feet deep at the skewbacks, and 9 feet wide When the keystone of the crown had been lowered into place and riveted up, the suspended cables would be slacked up and removed, and the whole suspension bridge taken down leaving the four great ribs of the arch ready for the erection of the supporting columns and the superstructure of the floor

The element of doubt which enters into this design is due to the system of erection adopted It is questionable whether, with the flexible support afforded by the suspension cable it would be possible to hold the voussoirs with that absolute accuracy and rigidity which is necessary It is well understood that during erection voussoirs must be kept in exact position by absolutely rigid falsework. Max am Endo was able to secure this rigidity by designing a frame-arch bridge, and tying back the successive sections, as they were added, to rigid anchorages on either shore Furthermore because of the great weight of the bridge, whose dead load over the whole 1,800-foot span is estimated at 26,000 tons the erection suspension bridge would have to be extremely heavy and costly It is but fair, however to quote Mr Worthington as stating that the estimates of the total cost of the structure indicate that it compares very favorably with the cost of a cantilever structure, even if the elaborate erection plant be considered to have no subsequent salvage value

## SIX THOUSAND MILES IN AN AEROPLANE.

IT is doubtful if any one, among the many thousands who have witnessed Hamilton's spectacular flights at Mineola, Long Island, and wondered at the bird like facility with which he performed his evolutions, realized that his success was the outcome of some six thousand miles of actual flying which he had done during the past six months

In qualifying for the degree of "bird man," Hamilton has served a long apprenticeship and has traversed the whole gamut of aeronautical experience. Of light but athletic build, quick but cool, and richly endowed with that intelligent daring which is so essential to success in aviation, he has probably had a more varied experience in the air than any other living man He has been carried up by kites, has not hesitated to cut loose in gliders at dizzy altitudes, and sweep through perilous distances to earth, and with balloons both spherical and dirigible he is altogether familiar With so much accumulated experience of the "feel of the air" at command, and with his rich endowment of the natural qualities of an aviator, it was inevitable that, when Hamilton took his seat in an aeroplane, he should quickly become one of the most, if not the most, experienced and successful exponents of the new art of human flight. Starting last November with a Curtiss machine, he has spent the intervening months in touring the country and teaching the public to what a pitch of perfection human flight has been carried Four days a week, for the past six or seven months, he has given exhibitions throughout the country, largely in the West and Southwest, making on each occasion four or five different flights Hamilton estimates that the total distance that he has flown through the pathless air in the intervening period is approximately six thousand miles, or sufficient to have carried him from New York to San Francisco and back Just here we should remark that it is fitting that a Hamilton should leave his impress so strongly on the pages of aeronautical history in the United States, since he is a direct descendant from John H Hamilton the brother of Alexander Hamilton, John H being the great great grandfather of the present Charles K. Hamilton

During a recent conversation, and at the request of [illegible] summed up con[illegible]rned during these [illegible]der a wide variety [illegible] scattered points in [illegible] wind," said Ham[illegible] all over again, [illegible]ly different from [illegible] but with coolness, [illegible]lem may be thor[illegible] in windy weather [illegible]ity Large crowds [illegible]other open spaces, [illegible]tly, when the ap[illegible] be winds of con[illegible]y times, and par[illegible]n winds that were [illegible] an hour, and over in [illegible] Arizona, for instance, the government gages showed that on the afternoon of my exhibition, the wind was blowing thirty three miles an hour My 8-cylinder, 50 horse-power Curtiss machine was brought out, and held in position facing the wind As the propeller revolutions increased, the thrust reached a point at which the machine began to lift, and on letting go, the crowd were astonished to see me apparently flying backward As the motor gained velocity, I first became stationary over the starting point, and then, with full power developed, traveled over the ground at a speed, relatively to the ground, of ten to fifteen miles an hour" On another occasion, at St. Joseph, Missouri, Hamilton rose and gave successful exhibitions in a wind which the local government anemometers registered at thirty nine miles an hour The young aviator considers that the bugaboo of the wind has been eliminated, and that from now on the skilled "bird man" will no longer wait around for three-fourths of a windy day in the hope of making a flight in the remaining fourth It is not the velocity of the wind, but the sudden changes in the velocity, that constitute the peril In a gusty twenty-five-mile wind, the velocity will suddenly change, in the puffs, from fifteen to twenty-five miles, a difference of ten miles per hour, and the range of difference increases with the increased speed of the wind.

AUTOMATIC CONTROL.—Asked for his opinion of the value of automatic control, such as might be afforded by pendulum action or by the gyroscope, Hamilton surprised us by affirming that he did not believe in such control "The pendulum effect would tend to become rhythmical, and the swing might be in the wrong direction at the critical time; on the other hand, the resistance of the gyroscope would be too rigid, and in sudden gusts it might be such as to cause the breaking of the planes by transverse bending strains." When flying in a gusty wind, the sudden upsetting forces must be met and resisted gradually, and the machine brought back to the normal position "with a loose curb" much as a skillful rider will control a spirited and sensitive horse. "The manipulations necessary to right an aeroplane are too complicated and inter-related to be capable of absolutely automatic control," said Hamilton, "as you will see from the following: If a puff hits the right side and lifts it, there are three distinct motions necessary to restore equilibrium. First the wing tips or ailerons must be set to counteract the lifting force; then the front horizontal rudder must be sharply depressed to throw the machine down and gain velocity; and thirdly, the rear vertical rudder must be swung over. These movements must be done with judgment and a delicate touch, and it is difficult for me to understand how the sensitive hand and intelligent mind of the aeronaut could be replaced by purely automatic appliances in a complicated evolution of this kind Furthermore, for perfect control, there must be a certain amount of anticipation of what is going to happen. Experience teaches the aviator to recognize different atmospheric conditions, he adjusts himself to these and in his manipulation of the control, anticipates the vagaries of the wind These are conditions which a purely automatic control could never meet."

WING SURFACE AND SPEED.—Hamilton looks for considerable increase in the speed of aeroplanes in the near future, and believes that some of the more powerful machines now being built will have made seventy miles an hour before the close of the present year As to the far future, the high-speed racing machine will probably be a monoplane, with long, narrow wings, affording small supporting surface relatively to the horse-power One of the most interesting facts developed during the varied experience of the past six months was the accidental verification of the important principle enunciated by Prof Langley, that the higher the speed of an aeroplane the less is the necessary sustaining surface It happened that in adjusting the engine at the commencement of an afternoon exhibition, the intake valves and carbureter caught fire, and several panels of the central covering of the upper and lower planes were burnt out, leaving only 150 out of 250 square feet of surface intact Rather than disappoint the assembled crowd of 8,000 people, Hamilton determined to try for a flight. Ordinarily, a 100 to 150-foot run would have been sufficient, but in this case it was not until the machine had run over 1,000 feet, and the engine was working at its maximum power, that the machine lifted Immediately Hamilton discovered that he was flying much faster than he had ever done before, which, of course, was strictly in accordance with the above-mentioned law of flight

Here is a hint that the racing machine of the future will have some system for reefing, which will allow the sustaining surface to be reduced, and skin friction eliminated as the speed increases Conversely when flying at El Paso, in the rarefied air due to an elevation of 3,980 feet, Hamilton found at first that he could not get off the ground at all The sustaining planes were lengthened, and 135 square feet were added to the normal area of 250 square feet. With this increase, the machine rose, and successful flights were accomplished. As the result of this experience, Hamilton believes that records of high flying in which the machine reaches the rarefied strata of air, should be accepted with considerable caution

---

Not very long ago, timber was selected entirely according to its external appearance The diameter and length of the piece, the straightness of grain, sometimes the weight, sufficed to determine both its commercial value and its destination At that time, on account of the difficulty of transportation, woods of local origin were almost exclusively employed. It is very different nowadays. With the increase in consumption and the decrease in the local production of wood, it has become necessary to transport timber of every variety and of many places of origin. Furthermore, the diversified industries of the present day require a corresponding diversity in the wood employed For one purpose, the important quality is hardness, for another, elasticity; for a third, ease of working, or resistance to attack by external agencies It is evident that very different qualities are required for an umbrella handle, a barrel stave, a billiard cue, a carriage frame, etc. The hand magnifying glass, which was first employed, has ceased to suffice for the exact determination of the structure of wood. The compound microscope is now used for the minute and careful examination of longitudinal and transverse sections of a specimen of timber, the commercial value and the proper industrial employment of which it is desired to determine. Fine-grain and thick-walled cells assure the solidity and resistance which are required in carpentry, and these qualities are incompatible with an abundance of parenchymatous tissue, filled with starch.

## ENGINEERING.

[illegible] for raising the Lighthouse Board to the dignity of a government bureau with a single head to manage it. A commissioner will [illegible] executive officer, and it is proposed to place the service in the hands of specially-trained civilians, who will not be liable to withdrawal for active service (as happens with army and navy officers) in case of war.

Referring to our recent article on the six Mallet freight compounds for the Delaware & Hudson Railroad, it is of interest to note that the four frames of the engines, each weighing about 8,000 pounds, are built of vanadium cast steel, having a tensile strength of 90,978 pounds per square inch and an elastic limit per square inch of 45,924 pounds, as determined by tests made while the frames were at the foundry.

A dispatch from Berlin states that the "Von der Tann," the first of the German dreadnought cruisers, reached, on her preliminary trials, a speed of 28 knots. This, if true, places her, in respect of speed, abreast of the British "Invincibles." The latest accounts credit her with carrying eight 11-inch guns disposed in four turrets, one forward, one aft, and two *en echelon* amidships. The displacement is about 19,000 tons.

Figures just compiled by the Pennsylvania Railroad system show that although in 1908 and 1909 its various lines carried a total of 299,762,658 passengers on its 24,000 miles of track, only one passenger was killed as a result of a train wreck. In other words, the chance of a passenger losing his life in an accident on the Pennsylvania Railroad system was one out of about 300,000,000

The naval board which conducted the tests of the ship brake recently fitted to the battleship "Indiana" reports that, though it will stop a vessel in a short distance, it is unsuitable for naval uses. It considers that unless the brake were constantly employed it would become clogged with barnacles. It would also increase the danger from torpedo attack, would be dangerous in close evolution, and would at all times somewhat retard the speed of a ship

Secretary of the Navy Meyer announces that he has approved the plans of the two new battleships which have been voted by the Senate and House. Each will be of 27,000 tons displacement and will carry an armament of ten of the new and extremely powerful 14-inch guns. In general appearance, in armor plan, and in disposition of the guns the new ships will resemble the "Florida," which was recently launched at the Brooklyn navy yard.

A comparison of the strength of the navies of the world in dreadnoughts shows that Great Britain has seventeen of 353,700 tons displacement, Germany thirteen of 275,000 tons, the United States ten of 221,650 tons, Japan six of 116,410 tons, Russia four of 92,000 tons, and Italy four of 80,000 tons. France has none of the strictly dreadnought type, either built or building. The above figures include both ships completed and those under construction

Hollow steel masts are not the only kind that carry away. The English racing yacht "Brynhild" recently lost her solid wooden mast which, in falling, seems to have driven through the light shell of the yacht, causing her to fill and sink in fifteen minutes The "Brynhild" was racing against the seventy-footers "Shamrock" and "White Heather." Usually the falling mast entirely clears the hull, as happened in the case of both "Columbia" and "Shamrock" I and III during their respective "America" cup racing seasons.

The board of engineers appointed by the Board of Estimate of this city to pass on the plan to distribute the new Catskill water supply in the various boroughs by means of a deep tunnel, one hundred feet or more below the surface, has reported that the tunnel would cost only $36,000,000, as against $47,000,000, which would be the cost of building a system of pipe lines. The construction is recommended on the grounds both of economical first cost and small future cost of maintenance

The four dreadnoughts which are being built for the Russian navy in Russian yards will have several novel features. They will be 590 feet long, 89 feet broad, of 23,000 tons displacement, and with 42,000 shaft horsepower are designed to make 23 knots. An armament of twelve 12-inch guns is to be mounted in four three-gun turrets placed on the center line. All turrets are on the upper deck, one forward, one between the smokestacks, another between the after smokestack and the mainmast, and the fourth on the quarter deck. The belt armor will be 8.8 inches maximum thickness, which is rather light, but the [illegible] [illegible] in the [illegible] war, belt and turret [illegible]. The armor, forward, is [illegible] deck, where it is [illegible]

## AERONAUTICS.

Capt. Baldwin and Joseph Seymour both gave excellent demonstrations on the 4th instant of their proficiency in flying their machines. The latter's biplane is a standard 25-horse-power Curtiss, while Capt. Baldwin has a Curtiss machine with a tail like the Farman and with a chain-driven propeller placed back of the planes and connected to the 25-horse-power motor. The propeller used is somewhat larger in diameter and of higher pitch than that ordinarily employed

Jacques de Lesseps crossed the Channel on the 21st day of May by way of Calais to Dover with a Blériot monoplane, and thereby won the Ruinart prize of 12 000 francs. Count de Lesseps started from the same downs at Barraques, near Calais, from which Blériot ascended on his memorable flight. The Count ascended at ten minutes to four o'clock in the presence of 2,000 spectators. His motor was a Gnome, revolving-cylinder engine of 50 horse-power At a height of 1,600 feet he was lost in a heavy fog The torpedo boat "Escopette," which performed a similar service for Blériot and Latham, accompanied him, but found it impossible to keep up De Lesseps was unable to adhere to his course, partly perhaps because of the fog, and as the "Escopette" entered Dover, no one knew anything at all of De Lesseps. He had landed about two miles to the north of Dover, near St. Margaret, and glided down a distance of about two miles after shutting off his motor He alighted at twenty two minutes after four, after a journey of forty-two minutes.

After Count de Lesseps's flight across the English Channel with the Blériot monoplane on May 21st (which was the second time this trip had been made by any aeroplane), the Hon Charles Stewart Rolls, who was the first Englishman to fly with a Wright biplane, on June 2nd succeeded in making a double crossing from England to France and return The start was made near Dover at 6 30 P M., and Mr Rolls covered the 21 miles to Sangatte near Calais in 35 minutes. After circling twice above the cliffs he returned to England, and landed some distance from the coast. Altogether he covered some 45 miles in about 75 min[illegible] ances of the [illegible] on another [illegible]

During the [illegible] were made at [illegible] are being used [illegible] ety and the [illegible] new aviators [illegible] T A. Baldwin, [illegible] Harmon made [illegible] His machine [illegible] and was slightly [illegible] present with [illegible] started to Mr. [illegible] distance from [illegible] whereabouts, [illegible] the propeller [illegible] climbed into [illegible] time he managed [illegible]

The latest and longest two-passenger cross-country flight was made on the 9th instant in France by Lieut Feguant and Capt Marconnet on a Henry Farman biplane Starting from Chalons at 4 40 A M the officers flew 176 kilometers (109¼ miles) cross country to the artillery park at Vincennes, which was reached at 7 10 This flight of two and one-half hours' duration was accomplished at a speed of 43¾ miles per hour. Capt. Marconnet was able to take photographs and make sketches that would have been of great strategic interest in time of war This is the first practical demonstration of the aeroplane for scouting purposes, in addition to its being a new world's record for cross-country flying with two men in the machine Another French aviator, Labouchère, flew for ten minutes with two passengers at Mourmelon on the same day

Previous to attempting a long-distance flight from New York to Philadelphia and back, Mr Hamilton gave some beautiful exhibitions of his skill in flying at Mineola the first week in June He would rise to a height of from 200 to 300 feet and circle about, at the same time swooping down to within 15 or 20 feet of the ground and suddenly rising again. When he was about to alight he would shut off the motor at a good height, and dive almost perpendicularly to the earth. When only 10 or 12 feet from the ground he would level up his machine, and make an extended glide only a few feet above the surface. He appeared to ride in the biplane as easily and with the same skill that a bareback rider rides his horse, and he seemed to take as much enjoyment from his dives and other pranks as did the large number of interested spectators. The machine he has used since last winter is the identical racer used by Mr Curtiss at Rheims. It is very fast, and has also demonstrated its ability to carry two people, since Mr. Hamilton took along a friend for a short spin on the 4th instant.

## SCIENCE.

Prof. Dr. Hergesell, of Strasburg, president of the International Commission on Scientific Aeronautics, will accompany Count Zeppelin on his expedition to Spitsbergen this summer, and will carry out a series of aerological observations in that vicinity For this reason it is proposed to hold the "international week" of kite and balloon observations, in which meteorological institutions in all parts of the world participate, from the 8th to the 13th of August, this year, instead of during November, as previously intended

Bernard Brunhes, director of the observatory of Puy-de-Dôme, and professor of physics in the faculty of sciences at Clermont-Ferrand, is dead at the age of 43 He was the author of many memoirs on physical and meteorological subjects, and of late had been prominent as the champion of the new methods of weather forecasting introduced by G Guilbert of Caen Brunhes endeavored to explain on theoretical grounds the methods deduced empirically by Guilbert, but the extensive polemics on this subject in the scientific journals have not led to any conclusive results

A fund has been established by Mrs E H Harriman for the collection of complete data on mammals and other animals of the North American continent Dr C Hart Merriam chief of the biological survey of the Department of Agriculture, will resign from the government service to take charge of the work The late Mr Harriman was intensely interested in natural history It was with his financial support that Dr Merriam visited Alaska a few years ago and collected data which added much to our geological and biological knowledge of that region

Attempts are being made to produce textile imitations, equal or superior to natural furs in color, gloss, and adaptability to the ever-changing dictates of fashion, and very much cheaper The substitution would have the further advantage of releasing the natural skins, especially goat skin, for use as leather Mohair and other long-staple wools are most suitable for this purpose A recent issue of the Faerber Zeitung contains a detailed description of the process of making imitation furs, including the operations of curling, dyeing with acid dyes, precipitating manga[illegible] dioxide on the fibers, steeping in alkali, and [illegible]forming the *bistre* shade produced by the manga[illegible] dioxide into green, blue or grayish brown

[illegible] has long been well known that the rural popula[illegible] is superior to the population of the cities, and [illegible] population of the agricultural eastern provinces of [illegible]many is superior to that of the manufacturing [illegible] provinces in regard to fitness for military [illegible]vice The forty-one large cities which contain one-[illegible] of the entire population of Germany, furnish only [illegible] per cent of its soldiers. Berlin makes the poorest [illegible]wing of all, furnishing only 39 per cent of the con[illegible]ent which it should furnish in accordance with its [illegible]ulation Hamburg furnishes 42 per cent of its [illegible] share, Bremen 65 per cent, Alsace-Lorraine 78 [illegible] cent The deficiencies are made up by the eastern [illegible]vinces. East Prussia furnishes 140 per cent of its [illegible] share, West Prussia and Posen 129 per cent, Pomerania 123 per cent, Saxony 134 per cent The average height of the recruits from the north of Germany exceeds that of the recruits from the south The average height for the whole empire is 66 inches, the average for Mecklenburg, Schleswig-Holstein, and Oldenburg is 66½ inches, and the average for Saxony and Silesia is only 65½ inches

Carborundum, which consists essentially of silicon carbide is produced in the electric furnace from a mixture of sand, coke, sawdust and common salt. With the exception of the diamond, carborundum is the hardest of all known substances, scratching even corundum, which is the hardest of natural stones except the diamond The commercial production of carborundum was first accomplished by Acheson, and the Carborundum Company which he founded produces in its works at Niagara Falls large quantities of carborundum, which is in great demand as a polishing and grinding material The carborundum hitherto produced contains a trace of uncombined carbon and consequently has a dark brown or black color, which makes it unsuitable for decorative purposes Recently however Frank Tone of the Carborundum Company, has devised a method of producing colorless and transparent crystals of carborundum, the refractive index of which is said to be even greater than that of the diamond These crystals are produced by charging the furnace with a mixture of 50 parts of pure carbon, 37 parts of quartz, 9 parts of sawdust, and 4 parts of salt. All trace of color is removed from the crystals by the addition of a small quantity of a metallic oxide, such as oxide of chromium As the refractive power of the diamond is one of its most valuable properties, and the carborundum crystals possess this property in a still higher degree, these new gems may become serious rivals of the diamond, if they can be produced in suitable shapes and sizes, and can be cut and polished like diamonds.

# A TELEPHONIC STETHOSCOPE

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

Telephone relay with casing removed

Great interest has been centered among British telephonic and medical circles in the interesting device invented by Mr S G Brown which was recently described before the Institution of Electrical Engineers The vital feature of this invention is the successful perfection of a telephone relay For many years inventors have been trying to develop such a relay but have been baffled by difficulties which many engineers have declared to be unsurmountable As the outcome of six years patient study and experiment however Mr Brown has achieved success as tests over [illegible] trunk telephone lines of Great Britain have strik[illegible] demonstrated

This relay which is shown in the accom[illegible] illustration and the design of which may be [illegible] from a reference to the explanatory diagram [illegible]

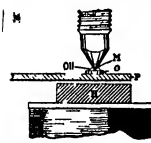

Fig 2 —The reed and contact pieces

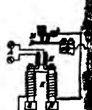

Fig. 3 —Electrical [illegible] of the relay.

veloped upon entirely new lines and is based upon the researches of Prof J J Thomson Earhart Kinsley and others concerning the flow of electrons across a microscopic air gap between two conducting surfaces at different potentials Earhart found that when the metallic circuit is broken by a minute opening of the order of 0 000 000 5 centimeter and the metal at the point of interruption is platinum the current will flow round the circuit and across the opening and when this interrupting space which Mr Brown terms the conduction space is slightly altered in length the resistance is varied and the value of the current flowing round the circuit is greatly affected This constitutes the fundamental basis of Mr Brown's invention for he points out that this conduction space is just what is wanted for the current carrying device of a telephone relay where microscopic mechanical movements have to be converted into large current changes But the dimensions of this conducting space are so minute that it is a difficult matter to insure and maintain it by mechanical means Therefore he devised a method whereby the current flowing across the conducting space effects its own adjustment in very much the same manner as the current that passes through an electric arc lamp strikes and maintains the length of the arc

In the diagram Fig 1 there is a permanent magnet *N* which is continued by soft iron poles right up to, but not touching the invar steel reed *P* Two sets of coil windings *H* and *K* are wound round these soft iron pole extensions and the telephone currents to be magnified circulate round the winding *H* and consequently by varying the magnetism set the reed *P* in vibration. There are top and bottom metal contact pieces *M* and *O* which are opened to an infinitesimal degree by the fine adjusting screw *W*, and by the action of the local current passing through the contact and around the winding *K* It is the action of the local current operating through this winding which forms and subsequently maintains the conduction space

This automatic adjustment is so absolutely perfect that the instrument may be turned upside down and yet produce scarcely any appreciable alteration in the value of the local current and certainly without exercising the slightest effect upon the action of the relay The regulating winding *K* however must not act when traversed by the rapidly varying telephonic currents and this end is assured by surrounding the iron under the coil by a closed circuited copper sheathing Eddy currents set up in this sheathing by mutual induction destroy the self induction of the coil In the instrument illustrated herewith the contact between the reed *P* and the contact pieces *M* and *O* is effected with metal pieces of hard osmium iridium alloy the top contact being pointed like a pencil (Fig 2) with the lower one flat and affixed to the reed Both are polished and work under a small drop of thin oil

The connections of the relay are shown in Fig 3 The telephone currents to be intensified enter by the terminals *A* and circulate through the winding *H* At *C* is a dry cell of normal voltage at *K* the low resistance regulating winding at *T* the telephone receiver of approximately 40 ohms resistance and at *D* an ampere meter or current indicator The relay usually acts at its best adjustment when the microphone contact is opened so as to reduce the local current to half its maximum value.

The extent to which it magnifies speech on ordinary lines is striking as trials have demonstrated and the great value of the invention is that the intensification of sound is secured without any perceptible loss [illegible] work with large [illegible] receiver in its [illegible]omfortable loud [illegible]d cable speaking [illegible]n this relay is [illegible] to any length [illegible]ow possible to [illegible] say supposing [illegible] direct speaking [illegible]he relay to the [illegible] be increased a [illegible]y being placed [illegible]ater at the end [illegible] as a receiver at [illegible] telephone cur[illegible] increased to [illegible] Should still [illegible] desired then it is only necessary to place two relays in tandem by which means magnification is increased to 400 times Moreover if a piece of soft rubber be made to touch the reed to assist the natural electrical damping of the reed the voice can be transmitted more distinctly and clearly than if the conversation were taking place in a room owing probably to the complete absence of echoes

The introduction of the local regulating winding *K* converts the metal contacts *M* and *O* into microphones of extreme delicacy securing a far finer degree of sensitiveness than could be obtained by light pressure between carbons In view of this fact Mr Brown continued his investigations and succeeded in evolving an electrical stethoscope whereby the sound of heart beats and other internal organs is very greatly magnified

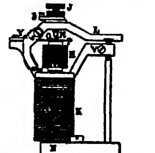

Fig. 1. View of the relay with the brass cover removed

A TELEPHONIC STETHOSCOPE.

Combined stethoscope and telephone relay.

Electric stethoscope with transmitter removed.

This stethoscope is highly ingenious and its design is shown diagrammatically in Fig 4 while the photographic illustration conveys an idea of its general appearance The transmitter if such it may be termed represented by *A* comprises a shallow brass cell faced with a thin diaphragm of ebonite This is placed upon the body in the region of the heart or other organ to be examined as with the ordinary instrument, and the sound of the beat or movement is conveyed to the ebonite diaphragm then to the air within the tube *B* to which the transmitter is connected setting the metal diaphragm *D* in vibration The contact pieces *M* and *O* are fashioned of osmium iridium *M* being mounted on the diaphragm *D* and *O* on the steel reed

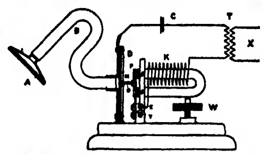

Fig 4.—Diagrammatic view of the stethoscope.

*P* The reed, together with the magnet *N S* is supported on a brass frame *E* pivoted or hinged at its lower support *Y* The conduction space is produced between the contacts *M* and *O* by the fine adjusting screw *W* and by the automatic action of the local current flowing from the cell *C* through the winding *K* and round the magnet A special telephone transformer of equal windings of about 20 ohms resistance is represented by *T* in the primary and in the secondary

With such an instrument as this the sound of the heart beat is intensified about three times But as such magnification is insufficient for practical purposes Mr Brown connects his telephone relay, as above described to the transformer wires *X* and the two instruments bring about a sound magnification of about 60 times or more

The instrument has been tested at the London Hospital where it was submitted to a number of complicated heart disease cases The physicians conceded that the instrument was far in advance of any stethoscope that they had previously used When it was applied directly to the heart the sounds in the telephone receiver were heard with uncomfortable loudness, and were even audible to the patient [illegible] as well as those standing around But as in such medical work other sounds in the human body, such as breathing which is [illegible] [illegible] with the heart beat [illegible] [illegible] ways and means for [illegible] these extraneous and [illegible] [illegible] metal diaphragm [illegible] and the reed [illegible] of the telephone relay are tuned to a [illegible] proportioning [illegible]

# A NEW SYSTEM OF COLOR PHOTOGRAPHY

Since the introduction of the Lumiere autochrome color-sensitive plate within the last three years, upon which a composite color picture is made at one operation direct in the camera, quite an impetus has been given to improvements in this line, which will overcome one of the drawbacks of the French process that is, the difficulty of securing duplicate color photographs except by successive exposures in the camera.

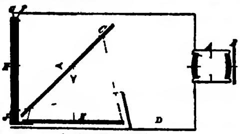
The new system we are about to describe has this particular feature, that duplicate color pictures can be obtained ad libitum from the first negative obtained in the camera. It has been perfected and simplified by Mr Frederick E Ives of this city and is quite unique in the way certain apparent difficulties are overcome

The process is based on the merging of the three primary colors, red, blue, and green It is not quite as simple in operation as the autochrome process but possesses the following definite advantages over that The sensitive plates used keep better developing successfully when several months old and cost but half as much as the autochrome plates the positive transparencies are made by a separate process from the finished negatives, thus permitting the making of any number of duplicates the transparencies transmit many times as much light as autochromes and are quite free from granularity so that they are perfectly adapted for use along with ordinary lantern slides in the lantern also for use in the stereoscopes the process also permits of local treatment to modify the colors when and where desired with extraordinary facility a feature which will be greatly appreciated by the artistic amateur

A special camera is required to make the triple negatives but it is very simple and can be used without change for all ordinary kinds of photography with plates or films

When it is desired to make a set of triple negatives for color photography a trichromatic plate pack consisting of three sensitised plates held together as one is used in the special plate holder instead of a single plate and is so disposed in the camera after the plate holder has been inserted as to produce by one exposure three negatives representing the three primary colors The plate pack consists of a red sensitive and a green sensitive plate with the sensitive or film surfaces in contact held between a backing card and a blue-sensitive plate which is hinged thereto by a strip of gummed paper When the pack is inserted in the plate holder the red and green-sensitive plates are retained by ledges and are pressed in close contact film against film by a spring on the lid but the blue-sensitive plate is made slightly shorter so that it falls or passes outward between the ledges. When the opaque slide of the plate holder is withdrawn in preparing for an exposure this plate falls outward into the camera resting on the bottom of the latter in a horizontal position at right angles to the other plates After this a yellow screen plate is dropped down from the camera roof by means of a lever on the exterior as shown in the diagram and the usual compensating screen is placed over the lens tube Then the exposure is made by means of the lens shutter which is said to be about as long as that required for an autochrome plate

Referring to the diagram, $A$ is the lens having a compensating color screen $B$ attached to it which equalizes the exposure for the three images and perfects the color selection $C$ is a hinged transparent



Interior arrangement of camera.

The camera, plate holder and carrying case

THE IVES ST[illegible]

yellow glass [illegible] dry plate [illegible] zontal position [illegible] downward by [illegible] image passes [illegible] green and [illegible] plates respe[illegible] tact with [illegible] the back [illegible] through [illegible] film on the red [illegible]

After [illegible] contact [illegible] outside [illegible] sition [illegible] lever on [illegible] the slide of the [illegible]

$H$ and $J$ represent an opaque backing card and a flexible hinge attached to the plate $E$ the plate $F$ being loose but held clamped between $H$ and $F$ when the pack is closed

The plate holder is inserted at the back of the camera under a ground glass frame held by springs in the usual way Focusing is done by moving the lens inward or outward through a tube on the front

It is evident from this arrangement that the image on each plate must be exactly the same but that two of them will be reversed one by reflection and the other because made through the glass side of the plate

In making positive duplicates on the film it is only necessary to reverse the position of the print from the positive-positioned negatives to make all three positive prints coincide when bound together between two glass plates to form one harmonious transparent colored picture The collodion positive film is so thin that accurate registration of the three films is not affected

The exposed plates are developed by time development as a unit held in a special rack they being separated open like the leaves of a book in a tank filled with an amidol developer The resulting negatives show no color but contain the color record in black and white and when finished are available at any time for making natural color transparencies

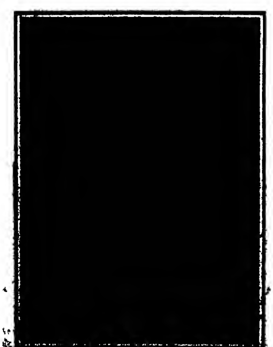
To make the transparent color prints the three negatives are placed side by side in a printing frame A sheet of collodion bearing a coating of bichromated fish glue is laid collodion side down on the negatives the back of the printing frame put in and then exposure made to light through the negatives—about one minute in clearest sunlight The exposed sheet is then removed from the frame clamped coated side up on a glass and developed by washing with water under a tap for a few seconds This gives three graduated low relief prints which are perfectly transparent but they are then cut apart and immersed in separate red blue and green dye baths for a few minutes (the dyes to be furnished in their proper colors) then rinsed off dried and superposed in register to make the complete natural color transparency The same negatives are available for color prints on paper but the processes for making color prints on paper are not yet [illegible] so simple and satisfactory as the transparency [illegible]

[illegible] appearance of the camera and plate holder and [illegible] case for carrying the apparatus is shown in the [illegible]ration It is quite compact and simple Ex[illegible] of these pictures both in the form of lantern [illegible] and stereoscopic transparencies have been shown [illegible] they possess a most pleasing brilliancy and [illegible]parency in coloring just as one would like to see [illegible] should be mentioned that Mr Ives [illegible] system succeeded in developing and perfecting [illegible] tone and half tone three-color processes several [illegible] ago and may be regarded as one of the pioneers [illegible] color photography For some of these discoveries [illegible] was awarded the Progress medal of the Royal [illegible]graphic Society of Great Britain the Elliott Cresson medal of the Franklin Institute and a special [illegible] from the Photographic Society of Philadelphia

We are informed that a company in this city under the style of Ives Inventions is soon to introduce this latest system which seems to be of a very practical character

# WIRELESS TIME SIGNALING TO SEA FROM THE EIFFEL TOWER

BY F HONORE



[illegible]

The wireless telegraphic station of the Eiffel Tower is now signaling Paris Observatory time to all vessels within a radius of 1 600 miles The present station is using 15 to 16 horse-power When the new installation whose completion was delayed by the recent floods is finished 100 horse power will be at the disposal of the engineers and the range will be doubled

A master clock which has long been used for the correction of marine chronometers is set up in a room of the observatory side by side with clocks that telegraph mean time to various centers in Paris and sidereal clocks which serve to regulate this mean time The master clock in question itself indicates mean time with reference to the meridian of Paris Inclosed in a glass case and suspended from a wall so thick that vibrations in masonry and variations in temperature cannot affect the mechanism it is corrected each day if necessary by means of a magnetic regulator The rod of the pendulum carries a magnet the lower end of which is spaced a few millimeters from a solenoid Depending upon the direction of the current which is sent through the solenoid, the magnet is attracted or repelled thus retarding or accelerating the beat of the pendulum In this manner a lost second is regained in thirty-six minutes

The clock is connected by wires with the key of the wireless station of the Eiffel Tower At midnight at 23:58, and at 12 04, the clockwork automatically

CLOCK WHICH AUTOMATICALLY TELEGRAPHS TIME.

completes a circuit, thus actuating a Morse key and causing Hertzian waves to be emitted

The observatory itself is not equipped to send wireless signals but it receives th m by means of a small aerial connected with telephonic receivers On the other hand by means of a Morse key in the circuit of an ordinary telegraph syste n independent of the clock the wireless apparatus on the Eiffel Tower can be operated from th obs rvatory

At the proper time each day an official dons a telephone headpiece and proceeds to the work of notifying vessels at sea of the correct time One finger on the Morse key his eye glued to the end of a reading telescope the official watches the beat of the pendulum At 11 59 he depresses the key and by means of agreed signals he attracts the attention of vessels in the range f a tl n At midnight the clock automatically signals the h ur This transmission of time is re p at i twice as we have said namely at 12 02 and at 12 4 preceded y other combinations of warning signals Hence vessels receive the time thrice in five m ut s

The officer on board the vessel at sea is similarly equipped with a telephone headpiece and he watches a hro ometer instead of a clock Making due allowance for possible errors of observation he estimates the error of his chronometer

### Esperanto and Ido

In last week s S PPL AMERICAN SUPPLEMENT we hro ici d the fact that a new international language has made its appearance which is a strictly scientific attempt made by an international commission of philosophers scientists and philologists to improve Esperanto and to provide the world with an artificial language which shall be tr ly international Some of our Esperantist friends have misunderstood the purpose of the commission and do not fully realize the scope of the improvement which has been effected They have written rather heated protests against the article which we published We are neither Esperantists nor Idoists but it seems to us that a fair examination of the International Commission s work must convince anyone of the valuable service which it rendered Below we republish Prof O Jespersen's [illegible] of the limitations of Esperanto taken from a [illegible] book published by the Délégation pour l'[illegible] d i e ang e aux laire internationale

Dr Zamenhof has given us an interesting [illegible] of the way in which his language gradually [illegible] in his mind while he was at the Warsaw [illegible] Before he arrived at the conviction that the [illegible] f r the vocab lary must be obtained from the [illegible] and Germanic languages, and that the already [illegible] ing stock of international words must be used [illegible] simply invented his words that is to say [illegible] them *it arb t ar ly* but with as much [illegible] system and brevity as possible Although he [illegible] noticed that such words are difficult to learn [illegible] more difficult to remember he has unfortunately [illegible] tained in the finished language a whole series [illegible] *à priori* formations which appear in words [illegible] frequent occurrence as who how where [illegible] everywhere etc The *nul tempe* and *pro* [illegible] chosen by the Delegation agree however m ch better with the general character of language than the *neniam* and *kial* of Dr Zamenhof

Some peculiarities may be accounted for by the Slavonic mother tongue of the author for example his preference for sibilants and diphthongs which is especially evident in the invented words (e g *chi* here *chiu* each *ech* even *ghi* that *ghis* until *gh* and *h* being pronounced as E *j* and *ch*) In an article in Zamenhof s Krestomatio I find for example (p 288) *kiuj tiuj senantauĵughaj kaj honestaj homoj kiuj anstatau filozofadi pri ghi* and (p 293) *tion chi ankora i ai tau la apero de la unua arta lingvo antau e dis kaj antaudirie chiuj tiuj eminentaj bogoj kiuj* etc The method of writing *x* is also Russian *ekzameni ekzemplo* etc and also *ekzpedi ekzplodi* also *kv* for *qu* French words with *oi* take *oa* in Esperanto when they are spelt in this way in Russian e g *trotuaro tualeto voalo* otherwise they are spelt with *oi* or *oj* e g *foiro fojo foino Nacio tradicio* etc instead of *-iono* is also Russian Russian usage has do btless also inspired such word formations as *elparoli* and *senkulpigi* instead of the international *pronounce* and *exkuse* (Russian *vygovorivat* and *izvin at* corresponding to German *ausspr chen* and *entschuldigen*) The peculiarity of using the adverb instead of the adjective in such cases as *estas necese vidi* it is necessary to see is probably to be ascribed to the correspondence of the Russian adverb with the neuter predicate adjective This rule cannot be permitted however in an international language because with a free word order it would be impossible to say whether *estas vere necese* means it is really necessary or it is necessarily true The compound perfect (*mi estas aminta*, I have loved = I am having love) reminds one of the Polish *kochal-em*. Finally the frequent use of the adjective (in -*a*) instead of the genitive (*Zamenhofa lingvo*) and of the two sorts of action expressed by *ch* and *ad* (*ch* [illegible] and [illegible] used in many cases where the simple *vidi* would be sufficient) are to be accounted for by Russian usage.

"Naturally I do not object to the importation of national peculiarities into the international auxiliary language when the latter is enriched thereby For example one must make use of the facility for forming compound words common to the Germanic and Slavonic languages in preference to the poverty of Romance languages in this respect and combine it with the more Romance characteristic of forming new words by means of derivative syllables. But peculiarities of national languages which render mutual comprehension and international usage difficult must be most carefully avoided.

The unpractical nature of the circumflexed letters has been indicated It may be remarked here however that in point of system Zamenhof s letters are very inferior to the similar ones employed in the Czech language since the parallelism in sound between *s* and *s s* and *ĵ dz* and *g* is disguised by the choice of letters This produces a very amateurish effect.

Beside the familiar parts of speech which are indicated by special terminations Zamenhof invented a new class characterised by the termination -*au* (*bon-t au almenau*) but the limits of this class which includes some but not all adverbs and prepositions are not clearly defined

Many words taken from existing languages are disguised almost after the fashion of Volapük *boji* French *aboyer* *parkere* French *par cœur* *s heit* German *schwitzen* English *sweat* char French *cor feruno* instead of *farin* *lerta*, French *alerte* (with a changed meaning) etc In this category is to be classed the astonishing *nepre* (entirely) which is derived from the Russian *nepremenno* just as if one were to take from the German word *unbedingt* the first two syllables and propose *unbe* as an international word instead of *absolute* The economy in the use of stems was carried much too far in Esperanto necessitating the employment of all sorts of compound words the discovery of whose meaning requires [illegible] the's brains The employ [illegible] as independ [illegible] a very [illegible] tly wanting [illegible] rect deriva [illegible] clearly indi [illegible] out from [illegible] to mean [illegible] so that [illegible] whereas [illegible] must [illegible] if a king [illegible] most important [illegible] which formed [illegible] Committee The [illegible] not prevent me [illegible] rvices of Zamen [illegible] of the best construction of an international language was not seriously discussed succeeded in producing one which was in many respects superior to the attempts of that time and which has proved in practice a serviceable though very imperfect means of international communication

### The Government and the Inventor

We recently commented upon a bill which is being considered by the House of Representatives, the purpose of which is to compensate those inventors whose inventions have been appropriated by the government. Since the publication of our remarks further testimony has been taken before the Committee on Patents, which reveals the hardships of an inventor who endeavors to create something which will be of benefit to his Government which only the Government can use and for which he has only one customer and that is the Government itself

One such invention is a torpedo system with a trolley guide which was conceived by Mr William S. Brewster while he was associated with Mr Edison It was at the time Mr Edison and Gardner Sims were perfecting the Edison Sims torpedo. Mr Brewster thought that instead of guiding the torpedo to its destination by its own mechanism, it could be guided by a trolley system He consulted Generals Newton and Abbot who were then prominent engineers in New York, about the system but he never took any patent out until advised to do so by a prominent officer in the War Department In 1896 he applied for a patent, which was issued in 1897 and which was offered to the War Department at practically the Department s own terms. The patent was granted for an invention which Mr Brewster could not use himself and which the Government might use if it found it serviceable. The offer was declined. [illegible] time of the Spanish war the invention [illegible] offered to the Government, with the [illegible] that the [illegible] in [illegible] ment was [illegible] off [illegible] note the [illegible] Mr Brewster [illegible] the Navy [illegible] closed a copy of [illegible] his patented trolley [illegible] in this torpedo [illegible] Hampton Roads. In so far as the Government [illegible] his trolley to guide the torpedo so that it should strike the target, Mr Brewster thought that it appropriated his invention One of Mr. Brewster s claims reads:

In a submarine torpedo system, a submerged cable constructed and adapted to constitute a track for guiding and controlling a torpedo in transit, and a torpedo connected thereto substantially as set forth.

This is so broad that the Government obviously infringed

The trolley system has since been used in testing the Davis torpedo gun Mr Brewster wrote again to the Navy Department asking for compensation for the use of his invention The Navy Department replied that the Electric Boat Company was making the tests of the Davis torpedo although as a matter of fact, the contests were actually conducted by officers of the navy Lieut. Commander Davis acknowledged the use of the guide saying that he did not know of the patent. Further correspondence with the Navy Department led to a controversy on the scope of the patent and the price demanded and finally ended in a flat refusal to pay

Another shining example is to be found in the utilization by the Government of Prof. R A. Fessenden s improvements in wireless communication Prof Fessenden was employed for about a year in the Weather Bureau One or two of his early inventions were produced during his employment but all of his later ones have been produced since Some of his patents have been the subject matter of suits in the Circuit Court of the United States and have been sustained. Infringements of them have been enjoined. The unsuccessful defendant in one suit tendered infringing wireless material to the Navy Department Prof Fessenden protested against the Navy Department s purchasing the material from the infringer calling its attention to the fact that a court of the United States had enjoined it from furnishing such material The Department replied rather autocratically that however that might be it preferred to purchase material in the cheapest market and leave it to the patentee and infringer to work out their salvation as best they could The infringer proceeded to furnish the material contracted for and delivered it to the Navy Department. The furnishing of that material was used as the basis for contempt proceedings. The officers of the infringing company were committed for contempt of court and were fined

There is now pending in the Supreme Court on writ of certiorari a case brought in the local court by the Krupp Company against General Crozier Chief of Ordnance in which it asks for an injunction to restrain him and his subordinates from making guns for the army according to the Krupp patent When the case came up for decision in the Court of Appeals of the District of Columbia the Court held that regardless of the fact that General Crozier was an officer of the United States army he derived no personal benefit from the use of the Krupp patents nevertheless he was an infringer The Krupp Company asked only for an injunction in this case and not for any compensation for the use made of its patent prior to the final decree An injunction pure and simple would not be a complete remedy in many cases General Crozier was merely the agent of the Ordnance Department. The Government of the United States derived the benefit and not he from the use of the Krupp inventions But that situation does not absolve the Government from paying.

Very often patents are being infringed by the Government without the knowledge of the patentee, because not every one can walk into a naval gun shop and see what is going on. Machines may be used in the Post Office for years without the fact being discovered A man may invent a new brand of chewing gum or a child's game and make a fortune He may invent a useful gun, or gun carriage, or a new style of armor, or a useful device in the Post Office that would save a great deal of money for the postal service, and get nothing at all for his time and labor except at the caprice or whim of some Government official.

So hard have been [illegible] that it must be admitted that the [illegible] the United [illegible] shown every [illegible] as they could. [illegible] the case of [illegible] back to [illegible] stated that the [illegible] the [illegible] [illegible]

[illegible] or corporation. Yet the Government ignores [illegible] and refuses to pay.

[illegible] such actions as inventors have succeeded in [illegible] against the United States have been largely [illegible] upon implied contracts. Thus in Burns's case (12 Wall, 246) it was held that the offer of the Govern ment to use a patented invention was a valid consider ation to support an action on an express contract for royalty. At first sight it might seem as if patentees already have protection in the remedy which they now have in the Court of Claims for the infringement of their rights by the Government. The courts have however found a difficulty standing in the way of granting to inventors a right to damages against the Government in cases where their patents have been used, in the fact that the statutes defining the juris diction of the Court of Claims confine it as a rule to cases arising upon contract with the Government. Hence the necessity of bringing actions under con tracts implied or expressed. Thus, in the case of Palmer (128 U S 262) the patentee invited the Gov ernment to adopt his invention and the Government did so. This was held to amount to an implied con tract. In the case of the Berdan Fire Arms Company (156 U S, 552) the patentee communicated his inven tion to the officers of the Government and they used it without expressly repudiating his title. These facts were held to give rise to the implication of a contract. The line is so slight as to be little more than for tuitous and the distinction is one that is utterly un worthy of a great government desiring to do impar tial justice to all citizens.

### New Trade Mark Bills

As the trade mark law now stands the registration by a corporation of a technical trade mark which may be its whole name or part of its name is impossible. The Court of Appeals has held in a recent decision published in the Official Gazette of July 7th 1908 in the case of Kentucky Distilleries and Warehouse Com pany vs Old Lexington Club Distilling Company that where the applicant is a corporation a trade name which is substantially a reproduction of the corporate name cannot be registered as a technical trade mark. That decision was regarded by the Patent Office as authority for making further decisions which are gen erally known in the profession as the decision in the case of the Champion Safety Lock Company the Amulet Chemical Company the Union Carbide Com pany and the Success Company.

The situation is anomalous. The Champion Safety Lock Company could not register its trade mark Champion under the law as it now stands or as it is now interpreted by the Court of Appeals because the word Champion is a conspicuous or salient part of the name of the company while John Smith who has no rights whatever with regard to the Champion mark may register the trade mark. Obviously this is unjust. A bill has been introduced for the express purpose of authorizing the Patent Office to grant such marks and to follow the letter of the law.

In cases such as the Union Carbide Company case there is, however another element which must be considered. In this case the word Union may be regarded as geographical and Carbide of course as descriptive so that possibly this is a case where the trade mark should not be registered unless it came under the ten year clause of the law. But Success and "Champion and Amulet and such are obviously valid technical trade marks.

Another instance can be found in the word Kodak as applied to photographic cameras. That word is undoubtedly a good trade mark. It has been sus tained by courts of this country and courts abroad. Yet it is ineligible to registration because the com pany that exploits the manufacture of that particular thing and has the ownership of that mark has come to be called the Eastman Kodak Company. It seems unfair that a trade mark which is a good mark should be unregistrable because it happens to be in corporated in the firm name or the corporate name of its owner.

The Committee on Patents of the House of Repre sentatives has also before it for consideration meas ures which have for their purpose the increasing or [illegible] of remedies for trade mark infringement, [illegible] the Patent Office to keep a more complete [illegible] of trade mark claims or rights.

The change proposed in one of the bills permits the [illegible] of non-technical marks if it can be alleged [illegible] [illegible]

# Correspondence.

### DISTILLING LICENSES

To the Editor of the SCIENTIFIC AMERICAN

I have seen in one of your SCIENTIFIC AMERICAN publications an article concerning Manufacturing Perfumes at Home. You recommend a still for the distillation of flowers also illustrate such a still. I wish to call your attention to the fact that such still must be registered with the collector of the district in which such still is located not only before opera tion begins but immediately after the still comes into the possession or custody of such person whether it be a new still distillery apparatus or not.

The law requires all stills set up to be registered if for use or not. This applies to all stills of what ever size and for whatever purpose intended. Any still which is not registered is subject to forfeiture to the United States together with all personal property in the possession or custody or under the control of such person and found in the building or in any yard or inclosure connected with the building in which the same may be set up. The person whose duty it is to register any still failing to do so is subject to fine and imprisonment under section 3258 Revised Statutes (Internal Revenue Department).

Kindly bring this to the attention of your sub scribers to avoid any difficulties.

### RAISING THE MAINE

To the Editor of the SCIENTIFIC AMERICAN

The recent act of Congress authorizing the raising of the wreck of the U S S Maine has given rise to many suggestions for raising her. The wreck has rested on the bottom of Havana harbor for nearly twelve years, and has doubtless settled considerably in the mud. The Maine was destroyed by the ex plosion of a submarine mine which caused the par tial explosion of two or more of the forward maga zines. Apart from the loss of life the results of this explosion were [illegible] from the bow to frame 41 was terribly [illegible]

Therefore it [illegible] frame 41 aft is [illegible] doubtful if anyth[illegible] tered forecastle [illegible] stroyed by dyna[illegible]

A new bow [illegible] which could be [illegible] similar thing [illegible] White Star line[illegible] lish coast. Her [illegible] which was held [illegible] under her own [illegible] docked. A new [illegible] fast, towed to [illegible] Within a year [illegible] regular duties [illegible] tralian steamers.

### HOW LARGE DOES THE SUN APPEAR TO ME?

To the Editor of the SCIENTIFIC AMERICAN

Ask ten people how large the sun looks to them when it is in mid heaven and you will get ten dif ferent opinions of its size which range from a silver dollar to a cart wheel. The varied opinions are due to the fact that there is nothing with which to com pare it when looked at by itself. Before any accu rate estimate of its size can be made we must have some known object with which to compare it.

Thus when the sun is on the horizon and appears to be close to houses trees and hills it looks very large. To some people it seems as large as a house or tree. Moreover there are more persons who will agree that it appears to be a certain fixed size under this condition than will agree when it is viewed at the zenith. The diversity of opinion in the latter case results from the inability of the eye to size up an isolated object.

This has been proved by projecting a narrow beam of light on a perfectly black non reflecting screen so placed that the observer could see nothing but the beam of light and had no way of judging his distance from the screen. The observations of several people under these conditions revealed the fact that there was no certainty about the length of the beam the appar ent length being estimated all the way from a few inches to several feet.

This being the case when the sun is in mid heaven how can its size be reduced to some uniform stand ard?

The most logical answer is found by representing it as a circle located at a fixed distance from the eye. The average reader holds the printed page about one foot from his eyes when reading. At this distance his size estimate fairly closely the size of the type or [illegible] illustration. In fact, a dozen good judges of di [illegible] can tell the size of an illustration, that does [illegible] inches, within a small fraction of an inch. These same men if asked to draw a circle on the sheet that would just cover the sun's disk if held between them and the sun at a distance of one foot from the eye would produce a series of circles of magnitudes ranging from a twenty five cent piece to a saucer.

The real size of the circle should be only three sixteenths of an inch in diameter.

The method of representing the sun's exact size by a circle one foot from the eye is simple. Take a smoked glass hold it one foot from the eye and scratch pin marks tangent to the sun's disk at the four quarters. When the diameter of the circle in closed within these marks is measured it will be found to be very close to three-sixteenths of an inch.

In other words if a circle of this size were drawn and in its area were reproduced in proportion to an average sun spot the observer would be able to ex amine the small dot at a distance of one foot from his eye with just about the same ease that he could examine the real spot on the sun through a smoked glass. Or again if the moon which is the same appar ent size as the sun and whose disk can be represented by the same small circle were to be reproduced in miniature within its area an observer holding it one foot from his eye could examine it with the same scrutiny that he could examine the full moon with his naked eye.

### The Current Supplement

The British Antarctic expedition has started on its journey for the South. Consequently the opening article of the current SUPPLEMENT No 1798 in which the equipment of the expedition is described will prove of interest. Not so many years ago in his famous book on education Herbert Spencer put forth a pow erful plea for the study of science. Nowadays how ever an advocacy of that kind is not called for and his book is at present largely of historic value only. Since that time the pendulum has been swinging too far toward the scientific. Prof Albert G Keller in an article on Science and the Humanities argues for the inevitableness of the humanities and of humanity. He asserts not only that our lives may be enriched by the pursuit of [illegible] in diverse forms not only that our destinies must be impoverished by the re nunciation of all lines save one but also insists upon the more concrete contention that our special scientific work is bound to suffer as a consequence of the neglect [illegible] for which the humanities stand. In all parts of the civilized world the least [illegible] [illegible] population from a physical and mental [illegible] and [illegible] is producing more numerous progeny and [illegible] would seem that unless means can be devised to stay this flood of the unfit in the course of time the entire race must descend to a lower level as regards physical and mental qualities. Of late the aid of eugenics and more recently still that of Mendelism has been invoked to keep the race at a high standard. The methods adopted are outlined in an article entitled Eugenics and Mendelism. Mr Paul F Bauder writes instructively on the quality of light. A sympathetic and appreciative biography is published of the late Sir William Huggins. Elihu Thomson contributes a thoughtful paper on atmospheric electricity. One of the most interesting problems of archæology has been solved by the recent excavations at Alesia that an cient city of Gaul where Vercingetorix headed 80 000 of his countrymen in a last gallant though futile at tempt to stem the advance of the victorious legions of Cæsar. The wonders of these excavations are told in an interesting article Mr Leon A Hackett contributes a very exhaustive paper on the processes of cotton spinning.

The removal of ashes by conveying them to a waste bank hydraulically is done in connection with the temporary plant built to supply power during the construction of the Rainbow Falls hydro-electric de velopment of the Great Falls Water Power and Town site Company on the Missouri River near Great Falls Mont. The power house is [illegible] the side of a hill di rectly above the edge of the river bank. The bitumin ous coal used is dumped by gravity from cars on a trestle to a bin at the rear of the firing floor of the boiler room and runs down on this floor from which it is fed by hand to the furnaces. As the ashes fall through the grates they are drawn out into a trans verse concrete-lined trench in the firing floor. This trench is sloped to one side of the building where it connects with a flume extending on a grade of about five per cent to the edge of the river bank. When the grates are cleaned the ashes are pulled into the trench and a hose stream turned into the latter to start them. They are thus picked up by and car ried out to the river through the flume only a small amount of water being required. No difficulty is ex perienced from clogging in the trench or flume and the current in the river prevents an accumulation at the edge of the bank.

# A GARDEN OF FUNGI

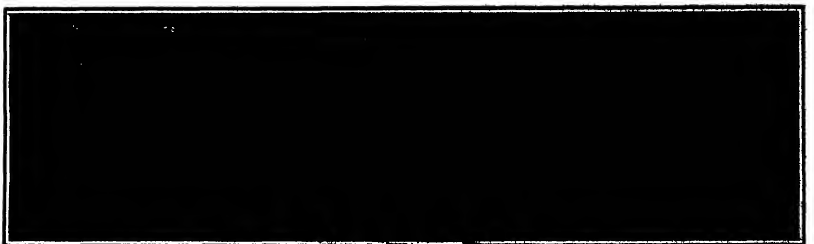
BY JACQUES BOYER

The Mycothèque annexed to the laboratory of cryptogamy of the Paris school of pharmacy is unquestionably the most original garden in the world It contains living specimens of 107 species of molds and allied fungi which M Bainier has patiently collected separated and cultivated on an appropriate medium

The fungi are sown or planted on pieces of licorice root in bottles of Bohemian glass about 3 inches in diameter and 8 inches high The mouth of the bottle is closed with a plug of cotton wool A glass rod the top of which is enlarged to form a cup in which the pieces of licorice root are placed passes through an India rubber stopper which is fitted to a hole in the bottom of the bottle The miniature greenhouse rests on a base of wood or porcelain filaments of *Penicillium* at first simple and later branched and resembling a brush bear chaplets of green gray yellow or rose-colored spores Minute drops of water often condense on the brush of *Penicillium claviforme* producing a very beautiful effect.

In order to obtain a pure and isolated species in each bottle interlopers of other species are carefully removed and the bottle if necessary is replanted two or three times The principal function of the collection is to supply the laboratory with living specimens of assured purity of type for use in research and in the illustration of lectures

The position of the curator is no sinecure When the nutrient material has been exhausted the fungus will perish unless special methods of preserving its life are adopted M Bainier having learned by experience [illegible] spores of each [illegible] arranges his [illegible] week one or [illegible] of cryptogams [illegible] retain their [illegible] while others die [illegible] has led to [illegible] published description [illegible] fact that the [illegible] separated from [illegible] organs of one [illegible] most interesting [illegible] Among the 27 [illegible] we observe *Mucor mucedo*, the common brown mold which attacks many substances and especially infests horse dung *Chlamydomucor orisae* and *Rhizopus orisae* which are used in the Orient in the production of fermented liquors from rice *Amylomyces Rouxii* or Chinese yeast which is used for the same purpose by the Chinese and was introduced into Europe by Dr Calmette director of the Pasteur Institute at Lille and a number of European species which likewise possess the two-fold power of transforming starch into glucose and of converting glucose into alcohol and carbon dioxide Among these species is *Mucor racemosus*, which is frequently seen growing on decaying vegetable matter *Phycomyces splendens* exhibits delicate filaments terminating in little balls. An allied species, *P nitens*, is employed to heighten the brilliancy of carmine by consuming the fatty ingredients of cochineal The single genus *Penicillium* is represented by 17 species. *P glaucum* is the common green mold which attacks bread, fruit and other articles of food Various sorts of cheese owe their characteristic flavors to species of *Penicillium*: Brie and Camembert to *P candidum* and *P album*, and Roquefort to *P virescens* which develops inside the cheese and produces the characteristic green veins



*Penicillium claviforme* — *Penicillium candidum* of Brie cheese — *Sterygmatocystis nigra*. [illegible] — *Fusarium* or melon fungus — *Aspergillus clavatus*. — *Phycomyces splendens*.

[illegible] JARS.

The licorice roots are deprived of their cork like bark in order to lay bare the yellow alburnum or sap wood which is filled with glycyrrhizin a saccharine substance which is very favorable to the development of mold fungi

Before the mold spores are sown the bottles containing the pieces of licorice root are sterilized by heating them to 248 deg. F. for one hour in an autoclave. One of the accompanying photographs shows M Bainier sowing the spores by removing the cotton plug and depositing a few spores on the licorice root by means of a platinum wire sheathed in a glass rod. The platinum wire is sterilized by passing it through the flame of a Bunsen burner before it is dipped in the mold culture and the cotton plug is instantly replaced after the sowing The bottle is then placed in one of the cases in the Mycothèque where the mycelium of the fungus rapidly permeates the licorice root which becomes covered with a growth which varies greatly in appearance according to the species

*Syncephalastrum* develops a dense mass of long grayish hairs *Isaria felina* resembles a shrub with many branches and *Acrostalagmus roseus* presents the appearance of a white felt hat The reproductive

The genus *Aspergillus* is represented by 6 species *A orisae* is used in Japan in the fermentation of the national beverage sake or rice beer *A fumigatus* attacks the mucous surfaces of the respiratory organs of birds and produces a pseudo-tuberculosis in pigeons fattened by the cramming process. There are 15 species of *Sterygmatocystis* including the celebrated *S nigra* (also called *Aspergillus niger*) which was studied so minutely by Raulin

The collection also contains various fungi which are parasitic upon insects including *Cordiceps* which infests caterpillars and *Botrytis* of which one species causes the muscarine disease of silkworms and others have been employed to destroy May beetles and locusts.

---

Alfred M Angot director of the meteorological service of France has reported to the Academy of Sciences that no exceptional variations in terrestrial magnetism or atmospheric electricity were observed in the neighborhood of Paris during the night of May 18th 19th when Halley's comet was in transit. The meteorological observations also failed to indicate any disturbance that could be attributed to the comet.

# THE TEMPERATURE OF THE STARS

BY JOSEPH BARTON

By means of his heterochrome stellar photometer M Charles Nordmann has succeeded in obtaining in addition to other interesting results measurements of the effective temperatures of certain stars The apparatus consists of a lateral attachment to the eye-piece of an equatorial telescope and like the Zollner photometer it allows the focal image of the star to be placed in juxtaposition to that of an artificial star This part of the apparatus contains two Nicol prisms the third Nicol and the quartz plate of Zoll ne s photometer being suppressed Furthermore between the focus and the eyepiece in the common path of the rays of the real and the artificial star is placed a sliding drum which carries interchangeable cells filled with colored liquids In this manner a series of mono-chromatic images of the real and art'ficial stars can be produced The photometric measurement is made by rendering the images of the two stars equally bright by turning the two Nicol prisms which are interposed in the path of the rays from the arti ficial star and are provided with graduated circles

The artificial star which performs the function of a secondary standard is obtained by converging upon a circular aperture the light of an Osram metallic filament lamp of four volts and one ampere This little lamp is operated by storage batteries and regu lated by means of a rheostat and an accurate volt meter There is no difficulty in maintaining the differ ences of potential between the lamp terminals con stant to within 1/100 volt by adjusting the rheostat once or twice per hour This corresponds to an in appreciable [illegible] star The [illegible] line dyes N[illegible] solutions wh[illegible] spectrum [illegible] taining red [illegible] parallel glass [illegible] 1 5 inch Th[illegible] spectrum [illegible] 490 millionth[illegible] mits the part [illegible] red and the [illegible] tion of the [illegible]

The photo[illegible] upon the in[illegible] various temperatures between 2550 deg F and 6 00 deg F these temperatures being measu d with the Féry pyrometer The first determinations ma l with the small horizontal equatorial of the obs va tory of Paris and the photometer described abov showed that this method of monochromatic imag s gives in a simple manner the measurements and ratios of the total luminosity of stars free from the [illegible] tive errors inherent to the older processes It [illegible]mits furthermore the solution of certain problems [illegible]hysical astronomy especially the meas rem nt f [illegible] temperatur s of stars T[illegible] d termination of [illegible]perature is based on t[illegible] fa t t[illegible] t[illegible] [illegible] luminous bodies are of equal intensity in their [illegible]ddle portion but of very different intensity at their [illegible] remities the body whose spectrum is brightest in [illegible] blue region possesses the higher temperatur [illegible]nce when the two spectra are compared with [illegible]ames of known temperatures the temperatures of [illegible] stars can be easily deduced from the optical obser[illegible]ations Nordmann finds for the temperature of the [illegible] the value of 3320 deg C (3608 deg F) This is

Standardizing the photometer with the aid of an electric furnace.

THE TEMPERATURE OF THE STARS

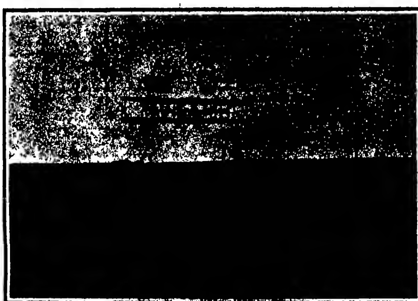
# The Flights of Rolls, De Lesseps, and Curtiss Compared

BY CARL DIENSTBACH

The "heavier-than-air machine" during the past few weeks has proved nearly as useful as the large modern airship, that has already been commercialized. When Blériot first flew across the English Channel, aeroplane traffic seemed near. But as nobody, not even his rivals in that attempt, repeated the feat, his performance gradually lost its convincing quality. In Germany his feat was dubbed a "mere piece of good luck." When, however, during the last few weeks, the Channel was not only crossed again on a Blériot machine, but in quick succession the whole navigable length of the Hudson was covered in a splendid high-speed flight, and when on the heels of that triumph the Channel was crossed and recrossed in a single flight, everyone realized that the aeroplane had entered upon a wider field of useful ness and that it was indeed a vehicle which is destined to be the pleasure conveyance of the future. The three flights mentioned were all over established routes of the liveliest traffic. They all required a machine which would not fail, under penalty of falling into the water, and they were all between rocks or precipitous mountain sides, which made it a problem to land in case of emergency, and which influenced the air currents in a way as yet so little known that even a zephyr might become formidable. That they were successfully accomplished by machines of so widely different types as the Blériot monoplane and the Curtiss and Wright biplanes shows to what extent the technics of flying machine construction have advanced within the past year. They especially emphasize the immense progress that has been made with regard to the heart of an aeroplane—its motor.

It seems now certain that the aeroplane motor will merely repeat the history of the automobile engine. It offers certainly a more formidable problem, but it seems now assured that the continuous falling of the early flight motors was due less to the inherent difficulties under which they had to work—running almost continuously at top-load—than to inexperience of the makers. It should be pointed out that the Curtiss and a Blériot machine alike flew with half the power with which they were provided for these trips. They were not larger than the standard type but De Lesseps had a 50 horse-power Gnome motor in place of the 24 horse-power Anzani with which Blériot flew across, and Curtiss also a 50 horse-power eight-cylinder motor against the usual 25 horse-power four-cylinder engine of a Curtiss biplane. Capt. Rolls had made no attempt to double the motive power of his Wright machine, but as he was flying alone he had considerable reserve force at his disposal. These were all machines capable of carrying a passenger, but flying with only the pilot aboard. Consequently the motors were not running continuously at top-load any more than automobile motors. Count de Lesseps used his power sparingly. He made little better time than Blériot. Even Curtiss, who was beating the "Twentieth Century Limited," says he rarely opened the throttle wide.

There is another feature common to these flights, to which their success must be ascribed just as much as to more reliable motive power. It is the evolution of high flying. For trips of this nature a great elevation has the very obvious advantage of easy reckoning. De Lesseps flew in a fog, yet, in contrast to Blériot, he was almost always in sight of land, at an altitude of a thousand feet, as compared with Blériot's 300. From the same superior level Curtiss saw the scenery spread below him like a chart. He could make short cuts, pick his landings, and easily decide where best to lay his course. Flying high greatly simplifies the pilot's task, where low flying would add to the difficulties of balancing, the difficulty of following a more or less circuitous course while dodging obstacles. It means something like the strain on a bicycle rider, who with his eyes glued to a country road, tries unceasingly to pick out a path. Though a flying pilot does not fear actual contact with objects below there still remains the need of allowing for leeway in case of wind gusts, irregularities of the motor or swaying the machine. The principal advantage of being able to go high is, however, in the increased "range" it gives in dominating the air itself.



Rolls in his Wright [illegible] before crossing the Channel.

De Lesseps in his Blériot monoplane flying across the Channel.

THE SECOND AND THIRD AEROPLANES TO FLY ACROSS THE ENGLISH CHANNEL.

Aviators are fast realizing that it is better to escape aerial disturbances than to fight them. This tends to prevent them from following any route that approaches the confined character of a roadway. The really favorable lanes of flight may be found only if the machine, unfettered, can pick its path at any level up to a thousand feet or more. The importance of flying very high across the Channel was understood by Latham, but not by Blériot, who ran into an aerial maelstrom when trying to land. De Lesseps and Rolls, who [illegible] crossed the very edge of the cliffs, [illegible] above this trap, escaped all danger of [illegible] the violent air-surf that beats against [illegible] of these rocky walls not less [illegible] the sea beats against their base. As the [illegible] was made in [illegible] some distance [illegible] beautiful [illegible] in France [illegible] these tactics. Curtiss, flying along a deep cut river valley, with a narrow base, but much wider in its higher part and surrounded by high, irregularly grouped hills, densely wooded, wisely resorted to the very opposite maneuver of skimming the surface of the water. He had no doubt learned this trick while flying above Lake Keuka. The Hudson River is known as the "American Rhine," but the long narrow valley of Lake Keuka reminds one of the German Rhine still more strongly with its long rows of vineyards along its steep sides, and the massive masonry of the wine cellars vaguely suggesting the ruins of old castles. If weather conditions are similar to those of the bright Sunday when Curtiss made his epoch-making flight to New York, the greatest safety from the air's billows is indeed found next to the water in such a river valley.

As a feat of navigation Curtiss's flight excelled De Lesseps's and Rolls's journeys across the sea. He had to deal with much more varied conditions of the air, just as changing as the topography of the landscape over which he was passing. It is not surprising that on his long trip he encountered that bugbear of the aeroplane, descending currents, that was more familiar to aviators in the old days of the Lilienthal and Chanute-Herring gliding machines when the wind was rather sought than avoided. During the past few years of the power-driven machine, for good reason the reverse condition has been sought. Gliding in a calm is so uninteresting, the machine in "dead air" seems so inert and devoid of power, that Lilienthal, Pilcher, Herring, and Avery gladly preferred to risk the gusts instead. Curtiss only reiterates what Herring fourteen years ago so eloquently described, when he refers to a feeling at the pit of the stomach like that caused by a quick-starting elevator and to lightning changes in the level of flight of twenty to forty feet.

Curtiss's ingenious use of the horizontal rudder in meeting these disturbances by a "homoeopathic remedy," i. e., checking the descent by steering down and gaining speed, shows his great aptness for aeroplaning. In an interview with the author the Wright brothers indeed remarked as early as 1905, that to go up, it was at times necessary to steer down, but they did not publish such tricks of their trade. Modern aviators are rediscovering for themselves many a secret of the early "classics." Thus Mr. Curtiss is planning now to add a device which gives him a firmer hold on the machine at times, when under the impulse of descending air it is slipping faster away under him than gravity impels his own body, while in the original design of the same machine by Herring the method of handling the controls was such that the aviator could cling to it all the time just as firmly as to the first Herring glider, as adapted from Lilienthal. The method of supporting the body under the armpits was taken over in the [illegible] Chanute glider from this adaptation and [illegible] into the original design of the Herring-Curtiss aeroplane.

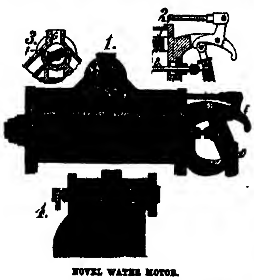
# Patent Department

## AN IMPROVED WATER MOTOR.

Pictured in the accompanying engraving is an improved hydraulic motor of the type embodying a cylinder and reciprocating piston. The motor comprises simple means for reversing the position of the valve at the end of each stroke of the piston, so that the motor will operate continuously and automatically. Fig. 1 shows the cylinder partly broken away to show the piston and piston rod. It will be observed that the piston rod *A* is hollow to receive the valve rod *B*. The inner end of the valve rod is threaded to receive a pair of adjusting nuts, which are adapted to strike the end of the piston bore when the piston moves forward, thus forcing the valve rod outward. On the return stroke of the piston a plug *C* carried thereby strikes the nuts on the valve rod, and moves the latter to its inner position. The valve rod passes through the head of the cylinder and engages a rocker frame *D*, pivoted on a bracket formed on the cylinder head. This rocker frame consists of two crossheads connected by a pair of coil springs. The upper crosshead is formed with a roller, as shown in Fig. 2, which is adapted to engage a rocker *E*. The latter is connected by a rod and crank to a valve in the valve chest. The valve is shown in Figs. 3 and 4. It consists of a diametrically disposed plate *F*, provided with suitable packings, which may be turned to connect the inlet port *G* with either one of the passages *H* or *J*, while the other of the passages is connected with the exhaust port *K*. In operation, when the valve is turned

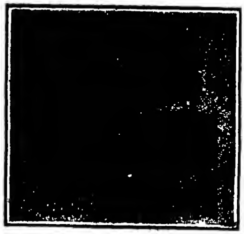


NOVEL WATER MOTOR.

to the position shown in Fig. 3, water will be admitted through the passage *H* to the left-hand side of the piston, forcing the latter toward the right and causing it, when it approaches the end of its stroke, to force the valve rod *B* outward. This will cause the rocker frame to swing out, making the roller carried thereby bear on the rocker arm *E*, and thus turn the valve *F*, so as to connect the port *J* with the inlet *G* and the passage *H* with the outlet port *K*. The springs on the rocker frame will cause the rocker arm to maintain its position until the valve rod *B* is acted upon by the plug *C* to return the parts to the position shown in Fig. 2. The inventor of this water motor is Mr John N. Hardy, of 411 West Second Avenue, Columbus, Ohio.

## STOVE PIPE AND THIMBLE.

A patent has just been issued on an improved type of thimble for use in flue openings. The thimble is so constructed as to be firmly attached to the chimney, and is provided with projections adapted to engage slots in the stove pipe, so as to fasten the latter securely in place, rendering the joint proof against leakage of smoke or gases of combustion. The thimble is preferably tapered, as indicated in the drawing at *A*. Between the thimble and the flue opening is a space which is filled with any suitable cement *B*, that will attach the thimble firmly to the chimney and act as a heat insulator to prevent transmission of heat from the thimble to any surrounding woodwork. The thimble is formed with projecting ears *C*, which [illegible] removed whenever desired by turning it before withdrawing it from the thimble. A slight modification of this fastening device consists in attaching the thimble to the chimney by means of spikes *F*, which take the place of the ears *C* as well as the ear *J*. The stove pipe is provided with tongues which are undercut, forming grooves in which the spikes are received when the pipe is given a partial turn. The



IMPROVED STOVE PIPE AND THIMBLE FOR FLUE OPENINGS.

pipe is formed with a bead adapted to engage the flange *B*, which forms a neat closure in case the pipe does not perfectly fit the thimble. When the pipe is withdrawn, the opening may be closed by means of a cap *G*, which is provided with grooves *H*, like those of the stove pipe. The inventor of this stove pipe and thimble is Mr. Ambrose P McGuirk, of Davenport, Iowa.

## EGG CANDLING AND PACKING MACHINE.

A machine for [illegible] automatically [illegible] is [illegible] to slide [illegible] *A* and [illegible] away to [illegible] to drop [illegible] of bridg[illegible] shaped as [illegible] eggs, and [illegible] is a lamp [illegible] upward [illegible] amined. [illegible] be rotated, [illegible] a pedal *D*. [illegible] of fingers, [illegible] the sockets [illegible] to slide [illegible] ing fingers [illegible] the eggs at [illegible] are connecte[illegible] erated to rel[illegible] pedal *D* is [illegible] drop into the egg crate. The [illegible] *B* is connected to a pair of bell cranks, which in turn are connected by parallel rods *H*. Mounted to slide vertically on the rod *H* is a pawl *I*, which engages a rack on the carriage that supports the egg case, so that the carriage is moved forward at each operation of the pedal *D* to bring the crate into position for a new row of eggs. The carriage slides on tracks *J*, which are connected by means of a pair of links to the base of the machine in such a way that when the lever *K* is operated they may be raised or lowered to regulate the height of the crate with respect to the guides *F*. As the pawl *I* is mounted to slide on the rod *H*, it will adjust itself to the rise and fall of the carriage. Mr Henry Pieper, of Uehling, Neb., is the inventor of this egg candling and packing machine.

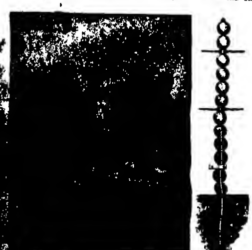
MACHINE FOR CANDLING AND PACKING EGGS.

## NOVEL CONCRETE FENCE POST

A fence post of concrete blocks which is of a decidedly unique type is illustrated in the accompanying engraving. It consists of a series of blocks of concrete devoid of sharp angles and preferably of spherical form. These are mounted one above the other on a rod which extends through openings in the spheres. The post thus has the appearance of a set of huge beads strung on a giant pin. At suitable intervals a bracket is attached to the rod, to which the fence wires are secured. These brackets are of very simple form, consisting of U-shaped straps of metal, which are clamped to the rod by means of a bolt. One of the legs of the U member is extended beyond the other, and is formed with an opening through which the fence wire is passed. Any number of these brackets may be arranged on the rod intermediate of the spheres. It is claimed for this fence post that it is particularly adapted for cattle lands because its flexibility prevents it from being knocked down, and the danger of the wires being broken is thus greatly lessened. As the blocks are spherical, they are less easily injured by frost or weather conditions. The fence post may easily be taken apart and packed in a small space for shipping. The inventor of this fence post is Mr Charles T Howell, of Glen Flora, Wis.

## Brief Notes on New Inventions.

The presence of a submarine boat is sometimes made known to the enemy by the train of bubbles that rise to the surface of the water from the gas-engine exhaust. These bubbles are readily discernible, and indicate the course which is being pursued, thus enabling the enemy to take measures for defense or a counter attack. In order to prevent a submarine boat from betraying its course in this way, an inventor has devised a method of retaining the exhaust gases, permitting them to escape only at irregular intervals in



UNIQUE CONCRETE FENCE POST

large quantities. Although the single large gas bubble thus produced would indicate the position of the submarine, it would not give any information as to the direction in which it was traveling or its rate of speed. The exhaust gases of the engine are led to a gas purifier and cooler, and then enriched with oxygen and passed through the engine again, so that the engine works in a closed cycle. An automatic valve serves to carry out the gases, when they reach too high a pressure, and conduct them to a receptacle, whence they may be released by a hand-operated valve whenever desired.

In case of fire, so the time-honored directions run, throw a mattress out the window and then jump down on it. As a mattress may not always be handy, an inventor of this city proposes that fire companies be equipped with mattress trucks for the accommodation of those who have been trapped in a burning building. He has invented a truck provided with a platform which carries a series of bed springs and mattresses and which, when brought to the scene of the fire, may be elevated to a considerable height, say to the second-story windows, and moved inward toward the building so as to bridge over the areaway. The inmates can then leap from their windows to the mattress.

There is nothing a fireman dreads more than a fire which produces volumes of dense smoke, for it is impossible for him to get near enough to the seat of the fire and to see clearly enough to direct the stream of water properly. Various devices to enable a fireman to breathe in such conditions have been proposed from time to time. A novel scheme of this sort has just been patented. It consists of a pair of bellows connected to a water wheel in the hose near the hydrant, and operated thereby to open and close alternately. Fresh air is thus pumped through an auxiliary pipe conducted along the main hose to a mask which is worn by the fireman.

In the raising of such vegetables as asparagus, green onions, pie plant, strawberries, and the like, it

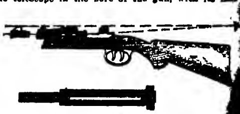
is customary to force the growth by covering the beds with glass. This is rather a cumbersome process, as it involves the construction of frames over the plants, which must be dismantled before they can be removed to a new location Furthermore, the heating device that is sometimes employed must be moved as well, which is rather an expensive operation. An improvement on these conditions has been suggested recently It consists in the use of a portable greenhouse and a separate portable heating plant, which may be connected to the heating pipes of the greenhouse The greenhouse is mounted on wheels, which travel on tracks or ways. The ways are temporarily laid when moving the greenhouse from one place to another

Two interesting patents on drinking cups have recently been issued One of them provides a folding-pocket drinking cup, which consists of a piece of flexible waterproof material folded upon itself to form a cup without any seams through which the water may leak The cup is covered by a strip of leather, and may be collapsed to form a flat package, so that it can be placed conveniently in the vest pocket. The other cup referred to is adapted particularly for use at soda fountains and public dispensaries of beverages It is formed of a band of paraffine paper connected by an overlapped joint The bottom of the cup is made out of a star-shaped blank, the points of which are folded up on the sides of the cup, and serve not only to attach the bottom to the cup, but to reinforce it The cup is made of tapering form to permit of nesting

Mr Dexter M Rogers, of Boston, Mass, has dedicated to the public an insect-destroying bomb upon which he has just secured a patent. The bomb contains dry poisons in powdered form, and is arranged to be exploded when it reaches a certain height after being discharged from a gun The poisonous powder is thus distributed in the air, and gradually settles down on the leaves of the trees which are infected with the insects This method of treating the trees possesses the advantage that the powder will reach all parts of the foliage, and is applied with a great saving of time and labor

### PATENTED ODDITIES.

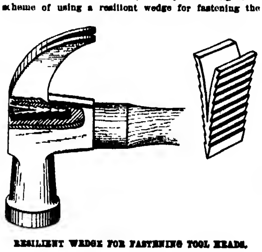
GUN BORE SIGHTING TELESCOPE.—A rather ingenious method of testing the sights of a gun has recently [illegible] patented by a German inventor It consists in [illegible] the telescope in the bore of the gun, with its line [illegible]



TELESCOPE FOR TESTING GUN SIGHTS.

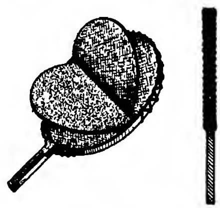
sight parallel to the axis of the bore The sighting device is then set to its zero position, and the gun [illegible] aimed at a distant object. The eye-piece of the telescope, which is shown in the enlarged sectional view, is fitted with a prism, so that the axis of sight intersects the line of aim at the eye In this way it is possible to make an observation by merely moving the eye to change the direction of vision, as indicated by the broken lines, whereas heretofore it has been necessary to move the head or even the entire body, in changing from an observation along the sights to one through the telescope

RESILIENT WEDGE FOR TOOL HANDLES.—An inventor in New Mexico has recently hit upon the ingenious scheme of using a resilient wedge for fastening the heads of tools upon the handles, the advantage of this being that when the wood is compressed through the use of the tool, the wedge will expand, and thus automatically tighten the handle The wedge as illustrated herewith is split, and is provided on opposite faces with ratchet teeth that serve to prevent its withdrawal from the wood. The tool head should also be formed with ratchet teeth inclined oppositely to those of the wedge, so as to prevent the handle from being withdrawn.



RESILIENT WEDGE FOR FASTENING TOOL HEADS.

AIR-COOLING FAN.—It is well known that the circulation of air increases the rate of evaporation, and thus cools a moist body It is for this reason that we use a fan to produce an artificial draught of air over the face and absorb moisture from the skin An inventor has recently hit upon the idea of improving the efficiency of the fan by providing it with a moist pad, so that the evaporation will cool the fan The fan is made up of a rattan frame, as shown in the accompanying drawing, which is covered with two layers of cloth, between which is a layer of felt. The cloth layers may be removed to permit of taking out the felt layer to moisten it Undoubtedly, when the fan is operated it will grow colder, by reason of the evaporation of moisture from the felt. It is a question, however, whether the added moisture in the air absorbed [illegible] to a certain extent de[illegible] from the [illegible]

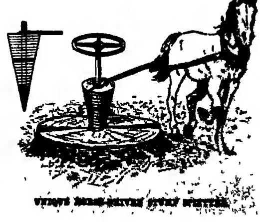


SELF-COOLING FAN.

[illegible] —It is [illegible] and dur[illegible] must fre[illegible] produce [illegible] accompanying sketch illustrates a method devised by a German inventor of producing this motion automatically Extending transversely across the drag is a rod or shaft, which at each end is provided with legs pointed at the ends. These legs are oppositely mounted so that, as the drag is drawn along, first one leg and then the other engages the ground, serving temporarily as a fulcrum about which the drag swings in an arc As a result, the drag is caused to pursue a zigzag course across the field.

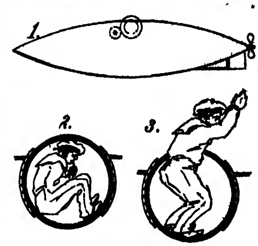
HARROW WITH AUTOMATIC LIFTER.

STUMP-SPLITTER.—The usual method of removing stumps of trees from the ground is to split them by the use of a wedge or a blast of dynamite The accompanying illustration [illegible] The wedge is in reality a large [illegible] provided at its lower end with a fine thread [illegible] ing the cone into the wood. The shaft of the [illegible] is provided with a hand wheel, by which it may be steadied and turned. Extending laterally from the shaft is a long arm, at the end of which a whiffletree is coupled. A horse may be hitched to the whiffletree, to turn the shaft and screw the cone into the stump When the stump is too large for the threaded cone on the shaft to split effectively, another cone-section may be added. After the stump has been split, by means of the cone, into a number of small parts, these parts can easily be excavated and removed



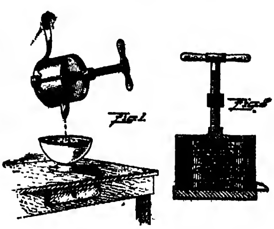
[illegible] HORSE-DRIVEN STUMP SPLITTER.

LIFE-SAVING HATCH FOR SUBMARINE BOATS.—When a submarine boat has been disabled and sunk, the occupants dare not attempt to escape, for if the hatch should be opened there would be an inrush of water, which would drown the crew before they could escape. An inventor has recently hit upon an idea, borrowed possibly from the revolving doors that are used in public buildings, whereby the crew can escape, one at a time, without admitting more than a measured quantity of water at each operation of the hatch. In this case a cylindrical hatch is used, provided with an opening at one side The hatch is mounted in water-tight bearings, and is connected by means of suitable gearing with a driving shaft, which will turn it on its axis, bringing the opening first into communication with the interior of the vessel, and then with the water outside To escape from the vessel, a man crawls into the hatch, as indicated in Fig 2, and then it is turned around to the position shown in Fig. 3, permitting him to dive upward through the water and escape



LIFE-SAVING HATCH FOR SUBMARINE BOATS.

BEEF-JUICE PRESS.—One of the best foods for invalids is the juice of rare beef, which is cut into fragments and pressed out by means of a small hand press. An inventor in France has recently devised a very simple press for this purpose, which allows of expressing the juice of a large amount of beef at a time. The press is similar to the ordinary type, being formed of a suitable receptacle with a plunger, which is forced down by a hand screw. Instead of operating the plunger for each piece of beef, the device is arranged to take a number of layers of beef, which are separated by disks of corrugated and perforated metal, as shown in the cross sectional view, Fig. 2. The press is provided with a spout at one side, through which the juice is drained out into a cup or bowl. After the [illegible]



IMPROVED BEEF-JUICE PRESS.

## [illegible] PATENTED INVENTIONS.

### Pertaining to Apparel.

FASTENING FOR HEEL-CUSHIONS.—W. L. [illegible], N. J. This invention relates to pneumatic heel cushions which are adapted to be worn on the inside of the shoe at the heel for the purpose of providing a resilient cushion for the heel. The object is to provide a cushion with improved means for use in securing the cushion against moving forwardly on the shoe.

SAFETY-PIN.—W B DANCY and C. B WESTCOTT, Savannah, Ga An object of the invention is to provide a strong pin which can be released or opened by a simple manipulation which involves the use of one hand only; which is so constructed that it can be opened without grasping or handling the pin itself in any way, and which when closed is securely held against accidental opening. It is particularly useful in surgical work for pinning bandages.

### Of Interest to Farmers.

CULTIVATOR PLOW.—G W PORANS, Geneseo, Ill. An object of the inventor is to provide a cultivator blade or shovel which will be more readily retained in ground that is rough, hard, or overgrown with weeds, than the ordinary blade. A further object is to provide a device in which the point of the blade is so constructed that it will readily enter the ground and does not have to be re-sharpened like the ordinary blade.

FIRELESS BROODER.—G H. LEE, Omaha, Neb. This invention has reference to fireless brooders such as are used by poultry brooders in raising chicks. The brooder is intended especially to be used without being heated by artificial means and the construction of the brooder is such as to retain the bodily heat which passes from the chicks.

PRESS FOR FRUIT.—T P MADDOX, Aztec New Mex This device maintains the covers of fruit crates in position to be secured in the body of the crate, and in securing the same The packing pressure for fruit may be applied while and in the act, of placing the cover in position The device holds the cover in position to be secured, which device carries in convenient position a receptacle for the fastening devices for securing the cover

### Of General Interest.

CORD-RETAINER FOR PACKAGES.—M SCHMIDT, New York, N Y The aim here is to so construct the package that after the cord is once tied and its ends properly protected by a knot protector no one can open the package without either breaking the same, mutilating the cord-protector, or cutting the cord The device also serves to reinforce the package so that the cord may be drawn very taut without liability of crushing in the edge of the package or box.

GUN MUFFLER.—J H STIMSON, Cooke, Mont. In the present patent the invention is an improvement in gun mufflers or silencers and has in view means to arrest the forward movement of the escaping powder gases and give the same a backward curling motion at successive points, whereby they escape gradually and produce a but slightly audible sound.

METAL SEAL.—S. STROH, Audrey House, Ely Place, London, E. C., England. This invention relates to metal seals adapted to be closed on cords and the like used for fastening packages. The aim is to provide a seal which shall be cheap to manufacture which can be used without the necessity of threading the cords through holes therein and which, when secured in position, cannot be tampered with without detection.

BOOK HOLDER.—W C TRAHER, London, Ontario, Canada Mr Traher's invention relates to book holders, and particularly to book-holders for stenographic and other note books, a plate being provided which is pivoted to a cover of a note book, a bent wire with fingers being pivoted to the plate, and the fingers being adapted to engage and hold the covers of the book relatively to each other.

HARNESS BACK PAD AND COLLAR-PAD.—L. P OVERHAUSER, San Diego, Cal. The pad is light yet duly flexible, and almost entirely relieves the friction between the portion resting in direct contact with the back of the animal and the portion to which the weight is applied by a strap or other means. The top plate is so arranged as to be limited in its endwise and lateral movement within certain limits. The weight is comparatively small.

COMPOUND FOR PRODUCING SILK-LIKE EFFECTS.—L. L. LILIENFELD, Zeltgasse 1, Vienna VIII, Austria. This invention relates to coloring matter for producing silk-like or pearl-luster effects, and such, for instance, as described in Letters Patent of the United States, formerly granted to Mr Lilienfeld. The aim is to provide a coloring matter for effects which applied to various articles made of wood, metal, paper, leather, textile fabrics, etc.

PHOTOGRAPHIC-PRINTING DEVICE.—T. [illegible], Me. The aim here is to produce a device adapted to be arranged in an opening through the wall of a dark room, [illegible] window, and arranged to [illegible] the device being provided [illegible] parts being so arranged as to be opened when the paper is in place.

HANDLE.—G LEMIEUX, Washburn, Wis. This invention is an improvement in handles for trunks and the like, in which the handles proper are foldable, and when required for use are extended or drawn out. An angle-iron serves for the support and the reception of the handle, and strengthens and protects the angles of the same.

WATER-GUARD FOR CHIMNEYS.—W F GARDNER, Atchison, Kan. In the erection of brick draft chimneys for houses, it is difficult to prevent rain water from passing down the walls of chimneys, and soiling the ceilings and side walls of rooms through which the chimneys pass. To overcome the defects, the inventor provides a peculiar construction of a water-guard in special combination with the walls of a chimney

COMBINED CARTRIDGE BANDOLEER, GUN REST, SHOULDER-STRAP, AND RECOIL-PAD.—R C WEST, Arbuckle, Cal In this equipment for soldiers and hunters, the bandoleer operates to retain the shoulder strap in place and the latter serves to carry the recoil pad and present it in proper position to receive the butt of the gun, the pad being preferably adapted to be detachably connected to either side of the strap in order that the appliance may be supported from either shoulder.

DEVICE FOR FASTENING BELTS.—G W SOUTHWICK, Noroton, Conn This improvement refers to belt joints of the hinge type, having wire eyes attached to the belt ends and a pintle engaging the eyes. For the purposes of the invention use is made of guiding means for guiding a piercing tool to provide the belt with apertures for the passage of the wire used for the hinge eye and looping means adjacent to the guiding means and around which the wire is passed to form the hinge eye.

### Hardware and Tools.

HAME-TUG.—A L. SADDLEMIRE, Knox, N Y The intention here is to provide a hame-tug arranged to insure a straight pull on the hame sticks and without danger of cutting or otherwise injuring [illegible] this purpose a metallic clip [illegible] stick and is provided with [illegible] tending pivot on which is [illegible] metallic end piece of the [illegible]

CAN OPENER.—J McD [illegible] In this case the purpose [illegible] to provide a can opener of [illegible] struction, wherein the blade [illegible] near the handle but is [illegible] away therefrom to permit [illegible] the blade to be sharpened [illegible] require.

### Heating and [illegible]

PORTABLE HEAT[illegible] Youngstown, Ohio. The [illegible] tion is to provide a device [illegible] ufacture, which is of [illegible] carried in the pocket of [illegible] is provided with two [illegible] bination with the body [illegible] which an object to be [illegible] tioned The device is [illegible] liquid fuel, such as alcohol

GAS-MAIN STOPPER.—P GOODMAN, [illegible] York, N Y This invention provides a projection in connection with the ring or eye carried by one of the handle bars, arranged to engage the inner wall of the main at the opening and prevent the bar from pulling out of the main under the action of the locking means, the projection and eye being adjustable along the length of the handle-bar to accommodate the stopper to the point at which it is placed in the main, the eye being arranged close to the outer wall of the main when the projection is engaged.

### Machines and Mechanical Devices.

PRESS-COPYING DEVICE.—H A BENNER, Washington, D C By this device clear and perfect copies may be made from type-writing made with ordinary copying ribbons and from writing made with ordinary copying inks, indelible pencils, etc., no special, heavily inked or quick-copying ribbons or inks being necessary, as in the ordinary copying devices of this type, thus obviating the smearing and blurring of letters before copying, and during the process of copying, as where quick-copying ribbons or inks are used.

BUSH PULLER.—J G O'DONNELL, Washington, D. C. The present invention is an improvement in the class of machines or implements adapted for grubbing or pulling bushes. The improvement is embodied in the roller and spring attachment and in draft devices applied to the lever The bush or sapling puller is distinguished by simplicity, lightness, ease in manipulation and effectiveness in operation.

GILL-BOX DRAWING-HEAD.—H. L. OPPERMANN, 21 [illegible], Leipzig, Germany In the drawing process of this invention an auxiliary hammer or cam is employed, by means of which the fallers are pressed down on to their intermediate position in such manner as to allow the withdrawal of the front row of pins from the sliver. In the construction [illegible] owing to the limited [illegible] on which the hammer has to work on the fallers, both are subject to much wear, so that the lowering of the fallers is uncertain, and as the hammer forms one piece with the gill screw, it has been necessary to replace it by a new screw This disadvantage the inventor overcomes.

FIRE-ESCAPE.—J W THOMPSON, Hinch cliff, Miss. The object here is to provide a fire escape with a drum, a worm wheel secured to a shaft journaled in the frame, a second shaft being provided for a gear wheel a worm the worm engaging the worm wheel, and the gear wheel on a third shaft, which has also a bevel gear which meshes with the bevel gear on a hand wheel, by which the mechanism is operated

VAULT-CLOSURE.—F UNCKRICH, Galion, Ohio. The invention refers to a closure intended for locking and hermetically sealing grave vaults and the like and consists of a door which can be locked in position at a door frame so that it cannot be opened from the outside without destroying the frame or door and which further can be so adjusted that if desired it can be opened from the outside without injury thereto, after it has been locked in position.

SANCTUARY-LAMP.—L M WILDE, North Walpole, N H In the present patent the invention is an improvement in sanctuary lamps and it has in view a motor driven mechanism to trim the carbon from the lamp wick during the burning of the lamp the said mechanism being inaudible in action and assembled compactly with the lamp proper

TRIGGER MECHANISM.—R. R WILLIAMS St Joseph, Mo This invention refers to trigger mechanism such as shown and described in Letters Patent of the U S., formerly granted to Mr Williams. The aim of the present invention is to provide certain new and useful improvements in trigger mechanisms, whereby an auxiliary can be readily set for action whenever it is desired to provide a sensitive action of the trigger mechanism

FLUID-OPERATED CONTROLLING MECHANISM.—J W ANDERSON, Sisson Cal. An important feature of the present invention involves the forming of the valve by relatively movable parts of the supply and exhaust conduits, and another important feature involves [illegible] by adjusting the device so as to make recesses of various sizes and shapes.

PROCESS FOR MAKING SHOES.—A H PARNELL, Halifax Pa In the present patent the invention has reference to improvements in shoes and is more particularly applicable to those shoes designed for the use of children in which a wedge is inserted under the heel seat to raise the heel while at the same time preserving the continuity of the bottom from the front to the extreme rear

FLEXIBLE CONNECTION.—F W BAADER Newark N J This invention pertains to certain improvements in flexible connection especially designed for use in connecting rotating members. The improved connection in itself constitutes a universal joint and may be used in any form of apparatus or machinery in which universal joints are desired It is particularly desirable for use in small flexible shafts.

TRANSMISSION-GEARING.—J K KOONS, Montgomery, Pa On the transmission shaft a plurality of gears is loosely mounted and means is provided for keying the gears to the shaft in succession or for freeing all the gears, a driven shaft has a single loose gear with shiftable keying and means, a keying means in one direction secures the gear on the driver shaft while a movement in the opposite direction directly connects the transmission shaft to the driven shaft. An examination of the patent is necessary for a full appreciation of the mechanism.

### Prime Movers and Their Accessories.

CARBURETER.—T J FAY, New York, N Y., and J M ELLSWORTH, Bernardsville, N J One of the objects of this improvement is to provide a device adapted to automatically control the supply of charge in the engine until said engine acquires a definite predetermined speed, at which time the device automatically admits additional air and automatically increases the quantity of said air as the speed of the engine increases above the predetermined limit.

GAS-ENGINE.—C BECKMANN, New York, N Y. The invention comprises a compact arrangement of cylinders about a central shaft, having inclined or skew wrist pins or cranks, and by means of the cranks the reciprocating movement of the pistons is transformed into a rotary movement at the shaft The wheel is so constructed that it operates as a valve controlling the admission and exhaust of the cylinders.

### Railways and Their Accessories.

EXTENSIBLE CONNECTION.—M I WELLS, Massillon Ohio This improvement has reference to extensible connections, and admits of general use the inventor's more particular intention being to provide a member built up of rods movable relatively to each other and provided with means for shifting the rods in order to vary their aggregate length

MINING CAR.—J BLAIR, St Benedict Pa The object here is to provide a car arranged to readily withstand the rough usage and jolting of the car when in use to maintain the axles in a right angled position relative to the longitudinal center line of the car with a view to insure proper running and to prevent the car being twisted out of shape when in use.

RAIL-JOINT.—W BARNETT, Hackettstown, N J The object of the present invention is to so construct the bearings of the cams on the bottom flanges of the fish plates that a downward pressure on either the cam or the nut will not tend to slide the cam outwardly, but the said flange will operate to support the cam in operative position

### Pertaining to Recreation.

PUZZLE.—C BRUNSWEIG New York N Y This device comprises an elongated box having an elevated runway along which small balls or shot may be guided from one end to the other At one end a plurality of pockets are provided which may receive the balls and in addition special means provide for returning the balls to the end remote from the pockets, and for bringing them into position for advancing them into the pockets.

GAME.—J R NIXON New Orleans, La The purpose of Mr Nixon's invention is to provide an amusing and instructive game wherein a field having hazards is provided and a balanced lever to one end of which is connected figures adapted to be moved into view when the lever is rocked by the weight of other figures movable over the field.

### Pertaining to Vehicles.

ADJUSTABLE PATTERN FOR TONGUE HOUNDS.—N J SMITH, Halstead, Kan In this instance the invention relates to certain improvements in patterns for use in the manufacture of tongue hounds for wagons and the aim is to provide a pattern so constructed as to permit of its use in marking out hounds of various different shapes and forms.

WIND-SHIELD.—E J MONTIGNY New York, N Y This improvement relates to wind shields for use in connection with automobiles and other rapidly moving vehicles the more particular purpose being to provide a wind shield comprising a two part sash adapted to fold neatly into the dash board which is of special structure in order to receive the shield

WAGON SEAT FASTENER.—L M LATTIMORE Shubert Neb This invention is embodied in devices adapted to support and clamp a seat detachably upon the sides of a wagon body In order to detach the seat from or adjust it on, the body it is necessary to first turn the roller to bring its cam out of contact with, or away from the wagon side In order to adapt the roller to a firm hold on the wagon side, the cam or eccentric portion thereof is provided with obtuse angled grooves.

BUGGY SHAFT TUG.—W G PETERS Danbury, N C The improvement is in buggy shaft tugs and the purpose of the inventor is to provide a device of this character which will obviate the necessity of slipping the tug over the end of the shaft and wherein the shaft will automatically enter and lock the tug when it is lowered into place

VEHICLE TRACTION MECHANISM.—J L. WILLIAMS, Ellsey Fla The principal objects which the present invention has in view are to provide a mechanism wherein the traction is obtained through members which are positive in their engagement with the ground, to provide a mechanism adapted to operate in broken and unequal ground and to provide a driving mechanism simple, elastic and durable

VEHICLE-WHEEL.—J W CARHART, Austin, Texas. In this patent the tire comprises a series of laminæ arranged side by side and provided with openings for dowel pins passing through the openings A ring plate is arranged on each side of the tire and against its inward face the adjacent ends of the pins abut bolts traversing the plates for securing them in place, and an elastic envelope on the outer face of the tire and lapped on the side thereof, the edges of the envelope abutting the edges of the plates, and nails driven through the envelop into the laminated body of the tire.

NOTE.—Copies of any of these patents will be furnished by Munn & Co for ten cents each. Please state the name of the patentee title of the invention, and date of this paper

# Notes and Queries.

## HINTS TO CORRESPONDENTS.

The full name and address must accompany all letters, or no attention will be paid thereto. This is solely for our information. *All* queries are answered by mail, and a *few* of the selected answers are afterward published in the paper. We cannot undertake to furnish information on matters of personal interest, without reasonable compensation. To answer questions which are not of general interest usually costs us from \$2.00 to \$3.00 each upward, and this sum should invariably be remitted in such cases. When there are questions involving building or other construction, or when calculations must be made, an estimate of the cost will be furnished upon request. We cannot give answers to examination papers, or decide wagers, nor can we undertake to solve mathematical problems of any description whatsoever. Do not use postal cards. Do not telephone inquiries, we cannot do justice to them.

Queries from this vicinity not answered within fourteen days should be repeated in full. Queries from points more remote will require a longer time.

We do not make chemical analyses, but we are always pleased to give the names of minerals which are submitted to us, when it is possible for us to do so. The minerals should be sent marked distinctly with the name of the sender, and should be sent fully prepaid.

Buyers wishing to purchase any article not advertised in our columns will be supplied with the addresses of the houses manufacturing or carrying the same, as soon as possible, or if we are unable to do so, their queries can be advertised in our special classified column.

Any books on any scientific or technical subject can be furnished. We solicit requests for quotations. The SCIENTIFIC AMERICAN SUPPLEMENTS referred to are mailed for ten cents each. Book and SUPPLEMENT catalogues will be sent free on request. A careful reading of these "Hints to Correspondents" will prevent any misconception as to the uses and will prevent abuses of this column.

(12242) J C G says: If the world was perfectly round and smooth and a belt was fitted around the center, perfectly tight, without a fraction of slack, and the belt when thus fitted was exactly 25,000 miles long, and this same belt was lengthened 18 feet, how much would this belt, after being thus lengthened stand out from the earth's surface, supposing that the earth was exactly in the center of the belt? I have a bet with some men that the belt will not stand out from the surface 2 86/100 feet at all places, and to convince them I am right, I have been referred to you as authority. They argue that the diameter of the belt after being lengthened will be six feet more than when measuring 25 000 miles. It is absurd I think, but at the same time I would be glad to know the fraction it would be supposed to leave the surface. A. We make it a rule not to settle bets but as this is a simple statement of fact, and the result *of the bet depends* not at all upon our judgment, which can be proved to you by anyone with a sufficient knowledge of simple arithmetic and the value of $\pi$ (the relation between the diameter of a circle and its circumference) and as you would doubtless obtain a decision elsewhere we do not like to seem discourteous by refusing to answer your question. The only consolation we can give you is that it was not a fair bet, as your opponents were betting on a certainty. Incredible as it may seem that the addition of so trifling an amount as 18 feet to a belt 25,000 miles long should increase its diameter nearly three feet, such is undoubtedly the case. It is figured as follows, and there is no way of figuring it otherwise. A more accurate value of $\pi$ say to ten instead of five places of decimals, would reduce the amount by an insignificant trifle. The difference of 0.14 between our result and that of your opponents is easily explained by their having used a different approximation of the value of $\pi$. The circumference 25 000 miles of the belt you suppose $\pi \times d = 3.14159\,d$; therefore the assumed diameter of the globe would be $\frac{25\,000}{3.14159}$ miles $= \frac{132{,}000\,000}{3.14159}$ feet = 41 422 0.29 feet. The diameter of the belt when its circumference is lengthened by 18 feet is $\frac{132\,000\,018}{3.14159}$ feet = 41,422 025 04,858 feet. The diameter is therefore increased in length by the difference = 5.04 858 feet and the lengthened belt will stand off from the globe by half that amount or 2.52,429 etc., feet.

(12243) K A R asks: Will you explain through the columns of your paper the following? A person said to me that the earth makes a complete 'wobble' once every 25,800 years, i. e., the North Pole changes its position in relation with the stars and consequently another star is designated the North Star. When asked what caused this wobble, he replied that it was similar to the wobbling of a top whose energy is nearly spent. The point that I do not understand is this. In the case of the top, after its rotation has decreased to a certain extent the attraction of gravity overcomes the gyroscopic force and therefore causes the top to wobble but in the case of the earth, there is no attraction other than that of the other heavenly bodies which is practically equal in all directions. Therefore why should the earth wobble? and is the rapidity of the rotation of the earth decreasing? A. The subject about which you inquire is called in the astronomies "the precession of the equinoxes." Any astronomy which may be in the library of your city will give you all the information you require on this matter. The poles of the heavens move, not visible, around the poles of the ecliptic in a vast period of 26,000 years. This causes the North Pole to move away from the Pole Star of our times, till in 12,500 years it will be 47 degrees away from it. Alpha Lyrae will then be the Pole Star. Precession is due to the attraction of the sun and the moon upon the ring of earth around the equator, as they are alternately on one side and on the other side of the ring. The attractive force of the sun and moon is combined with the centrifugal force of rotation of the earth to produce this extremely long period of precession. If you are not able to find any satisfactory work in your public library we can send you Todd's "New Astronomy" for \$1.50. The motion of precession is very like that of the spinning top when its axis is slightly out of plumb.

## NEW BOOKS, ETC.

MODERN COKING PRACTICE. By T H Byrom and J E. Christopher. London. Crosby Lockwood & Son. New York: The Norman W. Henley Publishing Company, 1910. 8vo.; 168 pp. Price, \$3.50 net.

The subject of coke manufacture is of rapidly increasing interest and significance, embracing as it does the recovery of valuable by-products in which scientific control is of the first importance. It has been the aim of the authors, in compiling this book, to produce one which shall be of use and benefit to those who are associated with, or interested in, the modern developments of the industry. While the book embodies, with some amplifications, a series of lectures delivered by J. E. Christopher, at the Wigan Technical College, to a class of men engaged on coke ovens, the authors entertain the hope that the work will be appreciated by students generally, and by many who are engaged in coke manufacture, or who contemplate the laying down of a by-product plant. Every endeavor has been [illegible] to present the facts as completely up [illegible] as possible, and if [illegible]

[illegible] terially from [illegible] formula on which [illegible] is based. A method to be universally acceptable must be based on theoretical formulæ and embody all of the requirements that occur in the building ordinances that govern construction in the various localities. It must be rapid and accurate in its applications, and if possible give at a glance the final result of changing any one or more of the assumed variables of design.

ATKINSON'S SIGN PAINTING UP TO NOW. By Frank H Atkinson. Chicago: Frederick J Drake & Co, 1910. Oblong 4to., 378 pp. Price, \$3.

This is a very handsome book on sign painting and the design of show cards with valuable alphabets, which contains 96 designs of lay-outs and accompanying color notes. There are 75 alphabets embracing all standard styles, their modifications and alterations, together with comprehensive text covering all practical phases of the art. There are a number of illustrations in the first part of the book showing how the work is actually done. These are specially valuable and we have not the same in any other book. The work seems to be eminently practical and the technical matter reflects the best usage in vogue at the present day.

THE LIFE OF WILLIAM THOMSON, BARON KELVIN OF LARGS. By Silvanus P. Thompson. Two volumes. New York and London: The Macmillan Company, 1910. 8vo.; 1,297 pp. Price, \$7.50 net.

One would naturally expect that a biography of Lord Kelvin, written by a prominent physicist, such as Silvanus P Thompson, would deal largely with the scientific accomplishments rather than the personal life of the subject, and this is, in a measure, true. A picture of Lord Kelvin's life and home relations has already been written by his own sister. The present volumes, however, take up the life of this great man from a different viewpoint, that is, in relation to his special work in the realms of science. The present biography was [illegible] Lord Kelvin. [illegible] much valuable information and many [illegible] reminiscences, which give the volumes [illegible] the importance of an autobiography, while at the same time due prominence is given to certain matters which might have been modestly passed over had Lord Kelvin been writing his own life story. The biography is made up to a large extent of manuscripts and scientific correspondence, and the author has wisely avoided placing his own interpretation upon them, preferring to let them speak for themselves. The work is intensely interesting from cover to cover, despite the fact that the work of Lord Kelvin was far in advance of the majority of his fellow men. The reader is brought into intimate association with the young man who struggled to the foreground in his college days, who in his very earliest days as a scientist did much to bring the theories of Joule into prominence, who as the foremost electrician in his time was the master mind in the problem of bridging the Atlantic Ocean by cable, and whose later work in the study of tides, mathematical astronomy, physics and electricity carried him far above any other man of his times. The two volumes are handsomely bound, and should make a most important and attractive addition to the library of the layman as well as the technical man.

MODERN ASSAYING. By J Reginald Smith. Edited by F W Braun. Philadelphia, 1910. 16mo.; 145 pp. Price, \$1.50.

The present book is not intended to be an exhaustive exposition of the subject, nor to take the place of the many excellent works on assaying, but rather to present in a concise, intelligible, untechnical way the science and methods for the assay of precious metals so that the reader may in the shortest possible time acquire the necessary knowledge to enable him to follow out practical work. They who have mastered the first ground work will soon gain all the rudiments of the science and use of the apparatus. The Editor has the advantage of being in the business of supplying assay and chemical laboratories. There are too many books on chemistry and assaying which are written by theorists. The book is [illegible] illustrated and may be considered [illegible] tribution to the subject.

[illegible] By H. Gernsback. [illegible] York: Modern Electrics [illegible] 1910. 12mo, 78 pp., 52 [illegible]

[illegible] book is to review what [illegible] wireless telephony, and to [illegible] investigate this interesting [illegible] wave communication [illegible] the editor of Modern [illegible] optimistic of the part that [illegible] to play in the imme[illegible] little of a practical nature [illegible] book, for the reason that [illegible] infancy. The amateur [illegible] establish a wireless tele[illegible] merely informed of the [illegible] can hardly as yet be [illegible] the practical stage.

[illegible] WORK, FURNITURE AND [illegible] Percy A. Wells and [illegible] London: B. T. Batsford. [illegible] York: John Lane Company. [illegible] 4to., 384 pp. Price, \$5 [illegible] 50 cents.

[illegible] account of the theory and practice in the production of all kinds of cabinet work and furniture, with chapters on the growth and progress of design and construction. It is illustrated by over 1,000 practical workshop drawings, photographs, and original designs. The book is particularly well made and the illustrations are of satisfactory size. There are many half-tones included in the text, showing exactly how the work is done. We have often wondered why it was that no one had gotten up a book showing how to use the hands in cabinet making, which is a most interesting trade or amusement, depending on whether the person is a professional cabinet maker or an amateur. Wood working in England has a vogue among amateurs which is entirely wanting in this country. This is probably owing to the fact that they lack proper instruction. This book will give them exactly the information which they are seeking. Among its many good points is a chronological chart giving names, periods, dates, general characteristics and proportions of chairs and seats in various styles. The whole book bears the impress of careful work, and there is little question but that it will have a considerable sale in this country among amateurs. There is also an excellent glossary.

"FLIGHT" MANUAL. A REFERENCE BOOK OF NOTES, FORMULÆ, AND TABLES. By Algernon E. Berriman. London: Published by "Flight," 1910. 16mo.; pocketbook size. Price, \$4.20.

Two main objects associate with this book: one is to form a [illegible] of what is hoped will become the standard work of reference on flight and aeronautics; the other is to provide a key to the articles appearing in the weekly periodical "Flight" whereby new [illegible] may be enabled to pick up the subject with facility. [illegible] the most important sections of the book are those dealing with [illegible] [illegible]

[illegible]

GLIMPSES ALONG THE WORLD'S [illegible] THE EYES OF A YOUNG [illegible] Grace Marion Stein. Philadelphia: The John C. Winston Company. [illegible] Illustrated. 8vo.; 481 pp. Price, \$2.

Of books of travel there seems to be no end, and every book seems to have more [illegible] a field of its own. The volume [illegible] very readable and profusely illustrated with engravings, the originals of which [illegible] have been selected with [illegible] than the usual care. The book is printed in large type on good paper and is worthy of an excellent sale.

APPLIED MECHANICS. By David Allan Low, Whitworth Scholar, M.I. Mech. E., Professor of Engineering, East London College, University of London. London, New York, Bombay, and Calcutta: Longmans, Green & Co., 1909. 551 pp., 359 illustrations. Price, \$2.75 net.

Mr. Low has succeeded in crowding a great deal of matter between the covers of this text book for engineering students. It embraces strength and elasticity of materials, the theory and design of structures, the theory of mechanics, and hydraulics. The matter is presented in a very clear and concise manner. The author believes thoroughly in the importance of exercises to fix a subject upon the student's mind. Accordingly a large part of the book is devoted to various exercises, there being 780 in all, 600 of which are original. The remainder have been selected from various examination papers. The book should occupy an important place in the student's library.

DESCRIPTIVE METEOROLOGY. By Willis L. Moore, LL.D., Sc.D. New York and London: D. Appleton & Co., 1910. 8vo.; 344 pp.; 45 charts and 31 illustrations. Price, \$3 net.

The author's present office as chief of the United States Weather Bureau, as well as his thirty odd years of experience in this connection, give the present work the stamp of authority. The purpose of the book is to instruct young men entering the service of the United States Weather Bureau, who have been hampered in the past by not having up-to-date text books on the rapidly progressing science of meteorology. However, the book has been written in such style as to appeal to the layman as well as the student. Technical terms have been carefully explained, for it is assumed that the reader knows little or nothing about the subject. Certainly every one is interested in the weather, and should welcome an opportunity such as this of making himself acquainted with the laws which govern the movements of storms. A chapter has been devoted to weather changes, which should enable the layman to make a good forecast with the aid of the daily official weather map. The study of meteorology is taken up in its broadest sense, with reference not only to the lowermost strata which directly concerns us, but to the entire depth of the earth's atmosphere, the latest study of the upper layers by means of sounding balloons and the part that is played by the sun and the motion of this planet about it.

THE STUDENT'S MATRICULATION GEOMETRY. Books 1-4. By Saradakanta Ganguly, M.A. Calcutta: The Students' Library. 12mo.; 248 pp.

This book has been written in strict conformity with the syllabus prescribed by the Calcutta University for the matriculation examination. A second edition of this book has just been issued, the first having been very well received by the teaching public.

CONIC SECTIONS MADE EASY. By Saradakanta Ganguly. Calcutta: Students' Library, 1909. 97 pp.

The author has written this book with a view to meeting the requirements of candidates for the intermediate examination of the Calcutta University. [illegible]

[illegible]

# INDEX OF INVENTIONS

For which Letters Patent of the United States were issued for the Week Ending June 7, 1910,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Abdominal adjuster, reducer, supporter, and retainer, A. Harris .... 960,805
Abrading machine, Bovell & Nolan .... 960,408
Account keeping apparatus, manifolding, C. F. Hadsall .... 960,861
Acetylene burner, F. M. Canfe .... 960,818
Acetylene generator and torch, portable, A. F. Jenkins .... 960,642
Acid, apparatus for concentrating sulfuric, Preslin & Hall .... 960,708
Acid, making formic, H. Howard .... 960,307
Acid, manufacturing carbonic, E. A. Behrens .... 960,786
Adding and recording machine, G. W. Dudley .... [illegible]
Adding machine, perpendicular and horizontal, C. E. W. Gardner .... 960,654
Adding machines, power drive for, O. C. Kreis, Jr. .... [illegible]
Adjustable bracket, T. Smith .... [illegible]
Advertising device, G. W. Hanlon .... [illegible]
Advertising device, J. Adelah .... [illegible]
Air brake angle cock connection and support, M. A. Garrett .... [illegible]
Air brake system, electropneumatic, G. Macloskie .... [illegible]
Air brake systems, angle cock support for, M. A. Garrett .... [illegible]
Air compressing and pumping apparatus, compound liquid piston, J. K. Sweeny .... 960,739
Air compressor, D. E. Allard .... 960,478
Air conditioning apparatus, Urbmer & Hedge .... [illegible]
Airship, E. B. Green .... [illegible]
Alarm. See Pressure gage alarm.
Aluminous material, purifying, L. E. Saunders .... 960,712
Anchor socket, L. Cowles .... [illegible]
Annealing furnace, J. D. Swindell .... 960,484
Annunciator and indicator, pneumatic, O. B. Winslow .... [illegible]
Annunciator, elevator, W. W. Savage .... [illegible]
Anthraquinone acridones, F. Ullmann .... 961,047
Anthraquinone di acridones, F. Ullmann .... 961,048
Ash shovel, E. Stevenson .... [illegible]
Automatic alarm and gas pressure cut-off device, O. C. Moon .... [illegible]
Automatic lubricator, W. Pfeifer .... [illegible]
Automatic ventilator, O. B. Reitz .... 961,016
Automobile brake, J. J. Stewarts .... [illegible]
Automobile headlight controller, H. A. [illegible] .... [illegible]
Automobile steering wheel, S. K. Hardy .... [illegible]
Awning, [illegible], W. J. O. Astrup .... [illegible]

[illegible]

Dye vat charging regulation, Mayeux & Verdon .... 960,602
Dynamite heater, O. Meissner .... 960,570
Dynamos, suspension for train lighting, J. A. Riniand .... [illegible]
Eaves trough protector, M. E. Daniels .... [illegible]
Electric accumulator, Marcelin & Goole .... 960,987
Electric cable, aerial, Ignor & Fredriksson .... 960,381
Electric conductor hanger, Conway & Hoffman .... 960,827
Electric conduit fitting, J. C. Vogel .... 960,744
Electric currents, system for the generation and distribution of, E. M. Newbold .... 960,693
Electric furnace, T. F. Baily .... 960,773
Electric furnace, J. W. Evans .... 960,662
Electric heater, J. C. Royce .... 960,400
Electric machine, dynamo, J. E. Noeggerath .... 960,383
Electric machine, dynamo, L. R. Underwood .... 960,449
Electric switch, E. M. Hewlett .... 960,324
Electrical separation apparatus, H. A. Wentworth .... 960,470
Electrically operated lock, H. S. Balliet .... 960,170
Electrode for welding, etc., W. A. Neff .... 960,681
Elevating machinery, A. T. Prescott .... [illegible]
Engine. See Blowing engine.
Engine, W. E. Blair .... 960,797
Engine controlling device, E. V. Longtine .... [illegible]
Engine cylinder, gas, F. H. Norton .... [illegible]
Engine igniting system, explosive, F. W. Springer .... [illegible]
Engine spark plug, explosive, J. P. White .... 960,753
Engine starter, hydrocarbon, C. Brisbois .... 960,483
Engine starting device, explosion, E. N. Pageisen .... 960,660
Engines, means for facilitating the starting of internal combustion, F. Purdy .... 961,077
Envelop, F. L. Norman .... 960,384
Eyeglass mounting, C. A. Hoffman 960,642, 960,824
Fan, automatic rocking chair, Lawson & Wildbur .... 960,967
Fans, cut-off for, T. O. Carlisle .... 960,815
Fare box, G. B. Kohler .... 961,070
Fare register rods, removable handle for, W. F. Fremsel .... 960,877
Fare slip holder, cash, H. E. Thomsen .... 960,733
Fastener, detachable, W. C. Schmidt .... 961,099
Faucet, J. A. Petro .... 960,665
Faucet, Porter & Thomas .... 961,011
Faucet, dispensing, M. E. Murphy .... 961,075
Faucet, two way, M. E. Koken .... 960,538
Faucets, price computing attachment for measuring, C. Jones .... 960,946
Feed heating and superheating boiler, S. A. Reeve .... 960,704
Feed trough, R. F. Miller .... 960,367
Feed water heating appliance, C. J. Mellin .... 960,394
Feed water purifier, boiler, L. Adler .... 961,000
Feeding bag, nose, J. N. Beenken .... 960,250
Fence post, A. W. Sprague .... 960,507
Fender, Littman & Leckie .... 960,078
File or binder, newspaper, C. E. Watterson .... 960,401
Film winder, E. A. Bircher .... 960,705
Filter, H. Brauner .... 960,367
Fire box door with draft device, J. A. Sandy .... 960,711
Fire escape, H. L. Cooper .... 960,510
Fire hose guide rack, S. B. Willis .... 961,054
Fire hydrants, discharge nozzle and independent cut-off valve for, A. L. Bizel .... 960,620
Firearm, automatic, R. Frommer .... [illegible]
[illegible] T. G. Jeppson .... [illegible]

[illegible]

Gate, W. A. Law .... 960,251
Gearing, F. Lindnagy .... 960,900
Gearing, C. P. Johnson .... 960,945
Gearing, transmission, C. A. McKiernan .... 960,572
Glass gathering machine, R. D. Brown .... 960,264
Glassware, fire polishing, A. J. Sanford .... 960,587
Glove reversing device, A. F. Imbrie .... 960,857
Glue, converting, I. M. Zimmerman .... 961,058
Governor, N. Lombard .... 960,308
Governor, emergency, F. Sammelman .... 960,411
Grab hook, C. W. Ebert .... 960,523
Grader and ditcher, road, Evans & West .... 960,296
Grain treating apparatus, H. B. Fox .... 961,068
Grinding tool, F. M. Clapp .... 960,821
Grinding device, A. M. McLaren .... 960,878
Grinding machine, Poitras & Caron .... 961,010
Gun, automatic, G. Colleoni .... 960,825
Gun stock, G. A. Stevens .... 961,041
Gyratory crusher, G. F. De Wein .... 961,064
Hair comb, J. H. Aker .... 960,248
Hame attachment, A. M. Lupton .... 960,272
Hame fastener, B. D. Simpson .... 960,425
Hammer, power, A. Beamiry .... 960,785
Hammer, steam, F. G. Gasche .... 960,891
Hammocks or other structures, sealing for couch, I. E. Palmer .... 961,004
Harvester, O. L. Perrigo .... 960,892
Harvester, A. R. Blewett .... 960,790
Hat hanger, G. Smith, Jr. .... 960,592
Hat sweat band, J. H. Beenken .... 960,251
Hay loader, S. K. Dennis .... 960,845
Hay press, G. F. Woodard .... 960,612
Hay turning machine of the drum type, L. Kenner .... 960,850
Headlight burner, C. M. Powers .... 961,012
Heating furnace, F. J. Droege .... 960,517
Heel, shoe, H. J. P. Boltger .... 960,708
Hinge for self-closing gates, J. Burlinghaub .... 960,298
Hoisting mechanism, J. Farrell .... 960,298
Hoop setting machine, Merriman & Stevens .... 960,765
Horn, J. Burke .... 960,811
Horse bonnet, J. M. Davies .... 960,840
Horse rake, J. T. Bell .... 961,253
Horseshoe, R. Wilbur .... 960,754
Horseshoe making machine, W. Peacock .... 960,880
Hydraulic motor, G. R. Franck .... 960,876
Hydrocarbon burner, L. A. Sherman .... 960,722
Ice cream freezer, B. Kaul .... 960,846
Igniting furnace for pulverous fuel, N. K. H. Birelund .... 960,392
Illuminating body, G. Weissmann .... 960,466
Incandescent mantle, inverted, C. K. Harding .... 960,638
Incubator, G. W. E. Zimmerman .... 960,476
Indicator. See Speed indicator.
Indicator, J. F. Marmark .... 960,058
Indoxyl, etc., making, Mugdan & Herrmann .... 960,671
Inhaler, H. Edde .... 960,525
Ink well, W. J. Somerville .... 960,798
Inkstand, F. M. Ashley .... 960,770
Insole trimming machine, A. Bates .... 960,751
Insole trimming machine, W. H. Keighley .... 960,952
Insecticide, J. W. Drummond .... 960,257
Insulation joint, A. McLean .... 960,377
Internal combustion engine, C. A. Bennett .... 960,864
Internal combustion engine, J. R. Gilson .... 960,538
Ironing table, J. A. Brosh .... 960,788
Jewels or ornaments to studs, means for securing, E. B. Kahn .... 960,667

Joint construction, D. S. Hunter .... 960,884
Joint fastening, C. H. Kimball .... 960,840
Journal bearings, lining, F. H. Howard .... 960,236
Key lock, interchangeable, A. W. Sibley .... 960,431
Kiln, W. Drayton .... 960,380
Kinetoscope, G. W. Bingham .... 960,794
Kinetoscope shutter, G. W. Bingham .... 960,795
Knitting machines, fabric cutting device for, F. B. Wildman .... 960,758
Ladder bracket, adjustable, F. T. Peters .... 960,580
Lamp, W. French .... 960,632
Lamp circuits, electric switch for incandescent, W. B. Crossland .... 960,636
Lamp, electric arc, Headland & Platle .... 960,911
Lamp mantles, attachment for incandescent, R. M. Dixon .... 960,861
Lamp, metallic filament electric glow, H. Kuzel .... 960,962
Lamp receptacle, incandescent, H. U. Badeau .... 961,808
Lamp socket, street, Bundy & Mauwaring .... 960,507
Lamp, safety, H. Feldmann .... 960,869
Lamp socket, twin, H. M. Sargent .... 960,414
Lamp support, electric, H. W. Ballbache .... 960,618
Lamp support, electric, J. Neple .... 960,888
Lamp, vapor, H. D. Wright .... 960,478
Lamps, shock absorbing and cord adjusting device for incandescent electric, H. A. Burnham .... 960,260
Lantern, projection, C. F. Dutton, Jr. .... 960,519
Last, locking hinged, A. E. Peckham .... 960,578
Latch, door, A. Nesselschwander .... 960,331
Latch, gate, J. B. Barnwell .... 960,777
Latch, gate, H. R. Elliott .... 960,858
Lathe cutter, W. J. McIntyre .... 960,678
Lathing, A. I. White .... 960,751
Lead joint runner, W. Vanderman .... 960,604
Leather pieces edgewise and otherwise operating upon the edges of material in sheet form, machine for joining, L. G. Weston .... 960,471
Level attachment for drills, F. Schiabe .... 960,718
Leveler, marker, and border machine combined, J. I. Wallace .... 960,454
Light securing means, T. Hoope, Jr. .... 961,038
Lighting fixture hanger, R. H. Wakefield .... 961,100
Link, spring, H. W. Sanford .... 961,023
Liquids, air controlled feed system for, R. J. Moore .... 960,866
Liquids, purification of, A. R. Williams .... 960,608
Loading device, F. Fifield .... 960,289
Lock, M. H. Farmer .... 960,868
Locking bolt, C. D. Obert .... 960,398
Locomotive ash pan dumping device, W. J. Brown .... 960,808
Locomotive cab window, J. W. Kales .... 960,861
Loom, A. J. Ibberelle .... 960,820
Loom embroidery attachment, weaving, L. Veyron .... 960,741
Loom shuttle race, K. Stola .... 960,423
Loom, tufted fabric, J. A. Clark .... 960,824
Looms, weft replenishing apparatus for weaving, L. Langenieux .... 960,965
Lubricating device, T. G. Kincaid .... 960,341
Lubricator, P. J. Sweeney .... 960,730
Machine tools, feed mechanism for spindles for, H. D. Evans .... 960,295
Magnet controller, lifting, J. F. Mots .... 960,995
Magnetic separator, W. B. Moore .... 960,688
Mail box, P. Reynolds .... 960,585
Manure loader, M. W. Bronson .... 960,490
Mask, face protecting, M. Hyslop .... 960,530
Massage apparatus, L. A. & C. M. Siebert .... 961,094
Massage devices, cap or head for, C. M. Siebert, Jr. .... 961,093
Match box holder and cigar cutter, combined, E. Diedenbach .... 961,101
Match receptacle and cigar cutter, single delivery, M. B. & J. N. Stowell .... 960,431
Match safe and cigar cutter combined, H. W. Behler .... 961,060
Measure, H. C. Harbridge .... 960,908
Measuring mechanism, rope, H. H. Hayes .... 960,321
Meat deflbering apparatus, H. P. Roberts .... 961,079
Mechanical movement, B. Hume .... 960,856
Medicinal preparation, I. Heinsinger .... 960,915
Metal bending tool, L. P. Hansen .... 960,910
Metal frame screen, J. B. Williams .... 961,052
Metal object compound, J. F. Monnot .... 960,872
Metal working apparatus, T. F. Baily .... 960,773
Metallurgical apparatus, Moore & Heskett .... 960,996
Metallurgical process, Moore & Heskett .... 960,997
Meters, automatic billing machine for, H. W. Gallagher .... 960,532
Milk dispensing vessel, M. H. H. Brinser .... 960,402
Milking apparatus pulsating device, E. N. Good .... 960,636
Mill. See Pulverizing mill.
Mining machine, coal, L. Kovatch .... 960,958
Molds, making resilient, A. A. Schmidt .... 960,714
Molding machine, K. Nelson .... 960,390
Molding machine, F. F. Walstrom .... 960,453
Molding machine, Lewis & Mannin .... 960,974
Molding marble, sand, J. Demster .... 960,844
Molding plastic materials, machine for, J. B. Leamon .... 960,969
Monotype machines, making matrix plates for, W. Nicholas .... 960,684
Mop head and wringer combined, W. J. Curry .... 960,627
Mop wringer, W. Monahan .... 960,871
Motor compressor, W. H. Lieber .... 961,065
Motor control, multiple voltage system of, H. W. Cheney .... 960,505
Motor controller, electric, E. Greenfield .... 960,609
Motors, means for automatically controlling electric, H. W. Leonard .... 960,971
Mower, V. P. Hollis .... 960,851
Mower, lawn, A. D. Case .... 960,502
Muffler, T. I. Forbes .... 960,530
Music leaf turner, M. & J. Schweihold .... 960,719
Musical instrument, stringed, F. L. Harmon .... 960,817
Nailing machines, wire feeding mechanism for, R. M. Cutter .... 960,275
Nest, hen's, H. A. Merkley .... 960,865
Nozzle for filters and similar devices, H. Reig .... 960,418
Nozzle, spraying, I. H. Ferry .... 961,006
Numbering machine, C. R. Smith .... 961,035
Nurling tool, J. Armstrong .... 960,769
Nut lock, G. F. Dobbs .... 960,284
Nut lock, J. S. Lafleur .... 960,349
Nut lock, N. J. Rogers .... 960,405
Nut lock, F. D. Cochran .... 960,307
Nut lock, J. F. Nicholson .... 960,990
Nut lock, H. S. Valle .... 961,049
Nut lock, J. I. Austin .... 961,060
Oil burner, K. A. Bright .... 960,491
Oil burner, crude, J. A. J. Latil .... 960,568
Oil burner, crude, C. Shaeffer .... 961,080
Oil can, J. Gallong .... 960,898
Organ pipe, A. H. Brook .... 960,263
Package, shipping, J. M. Alderfer .... 960,766
Paper bag machine, J. Merritt .... 960,684
Paper bags, suspending holder for, A. Guill .... 960,898
Paper hanger's board, F. H. Weller .... 960,468
Paper hanger's board or the like, F. H. Weller .... 960,469
Paper holder, O. P. Marshall .... 960,862
Paper holder, carbon, A. J. Rund .... 960,498
Paper holder, toilet, Hubbard & Beus .... 960,929
Paper makers, size for, A. W. Harrington .... 960,318
Paper treating composition, A. W. Harrington .... 960,319
Paper weight and pen extractor combined, N. O. Wicker .... 960,758
Pen, fountain, H. J. Marts .... 960,660
Pen, reservoir, W. W. Sanford .... 960,413
Penholder, D. D. Nure .... 960,252
Penholder, H. E. Moyer .... 960,373
Penholder, A. O. Sperry .... 960,595
Pencil, M. L. Schmits .... 960,588
Perambulator, folding, J. Kanabay .... 960,337
Percolator, O. Reig .... 960,419
Pessary, O. H. Sheppard .... 960,721
Phonograph record blanks, manufacture of, V. M. Harris .... 960,320
Phonograph reproducer, P. Weber, reissue .... 13,130
Photographic print and making same colored, F. E. Ives .... 960,939
Photographic printing mask, J. Fits, Jr. .... 960,301
Photometer, Sharp & Millar .... 960,420
Piano attachment for giving mandolin effects, J. Metzger .... 960,665
Pictures to stones and the like, transferring printed and other, A. L. de Roey .... 961,707
Piling cap, sheet, W. H. Warrington .... 960,746
Pills for the treatment of diabetes mellitus, A. Heinemann .... 960,914
Pin. See Clothes pin.
Pin tray, C. F. Brown .... 960,622
Pipe, W. E. Sharm .... 961,042
Pipe coupling, L. Miller .... 960,667

[illegible]

Well drilling machine, U. H. Waterman [illegible]

Wheels, separable rim for vehicle, T. C. Moll [illegible]

[illegible]

Window cleaning utensil, C. W. Coover [illegible]

Window screen, A. E. Pattison [illegible]

Wire stretcher, L. H. Cooper [illegible]

Wire winding machines, notching attachment for, C. W. Stancliff [illegible]

Wood bending machine, C. W. Elliott [illegible]

Wool washing machine and the like, F. G. Sargent [illegible]

Wrapper, J. Greenberg [illegible]

Wrench. See Pipe wrench.

Wrench, L. Panzer [illegible]

Yarn waxing device, N. R. Kahn [illegible]

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

### A TELEPHONIC STETHOSCOPE.

(Concluded from page 496.)

two diaphragms $A$ and $D$. In this manner all sound except that particularly desired is eliminated. Thus it is possible to hear only heart beats, or the distinctive sound characteristic of any other organ to the exclusion of all outside noises so that attention can be concentrated upon that essentially desired. When the instrument is tuned to diagnose the respiratory organs the passage of the air through the lungs is heard in the telephone as a rushing roar of wind.

With this instrument it is quite feasible for a physician to examine a patient stethoscopically from a distance over the ordinary telephone. [illegible] that is necessary is to conn[illegible] ratus with the telephone servi[illegible] manner it has been possible [illegible] the sound of heart beats [illegible] distances, and the supreme [illegible] direction was when the [illegible] placed on the heart of a [illegible] don, and the beats were [illegible] by physicians in the Isl[illegible] matter of 100 miles or [illegible] instrument is far more [illegible] than the stethoscope ordinar[illegible] if any noise is created in [illegible] which the examination is [illegible] out, it is very distinctly [illegible] ably heard at the receiving [illegible] viate the discomforts of this [illegible] possible, the instrument is [illegible] and should be used in a quiet [illegible] the tube $B$ and the diaphragm $A$ [illegible] moved and a funnel substituted, [illegible] strument will collect and intensify to an extreme degree the slightest sound, an ordinary conversation being converted into a deafening shout at the receiving station.

The instrument has also been adapted to other phases of work such as the electrophone and wireless telegraphy with similar success. In the former case when the receiver is connected to a trumpet the sounds are distributed throughout the room, while in connection with etheric telegraphy it has enabled impulses, which were so feeble as to be undetected, to be picked up, and distinctly read by the operator at some distance from his instrument.

### THE FLIGHTS OF ROLLS, DE LESSEPS AND CURTISS COMPARED.

(Continued from page 502.)

seat of one of these machines under any conditions.

De Lesseps used a 1910 Blériot for his channel flight. This model is not greatly changed from the machine that carried Blériot across to England. It is somewhat stronger in the framing and the power of the tail has been increased by enlarging both the stabilizing and the rudder surfaces, and by placing the stabilizer on the same level with the rudder. [illegible] rudder is slightly larger.

[illegible] flown in a French-built Wright machine. As he used a Short-[illegible]

(Continued on page 510.)

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES.

100 PER CENT profit selling the Lindsay soft inverted mantles; fit any inverted gasoline light. Steady customers in every town. Fine side line for salesmen. Vest pocket samples and prices on request. Lindsay Light Co. Dept. R, Chicago.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

## PATENTS FOR SALE

PATENT No. [illegible].—For sale or royalty. A hook and eye. No hump, the eye does it, and does it better. For further particulars address E. M. Cowles, Hartford Avenue, Milwaukee, Wis.

Inquiry No. 8987.—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

PATENT No. [illegible].—Breech mechanism. Much stronger than any other, for sale with inventions for increasing the rapidity of fire and accuracy of heavy ordnance. E. A. S. Hammar, 223 N. North St., Butler, Pa.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## WANTED

PRACTICING ATTORNEY of ten years' experience, would like to join forces with large manufacturing or contracting firm. Best of References. Address Lock Box 561, Syracuse, N. Y.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## SALE AND EXCHANGE.

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $60.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9045.—Wanted, the address of the Chapman Electric Purifying Co.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9060.—Wanted to buy machinery to manufacture seed corn racks.

## MISCELLANEOUS.

WE are about to complete a large contract for Taxi meters and are therefore in a position to take up experimental work, manufacture of fine instruments, parts for the same, dies, tips, etc. Precision Tool & Instrument Co., 5-15 Canal Place, New York City.

Inquiry No. 9075.—Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

Inquiry No. 9078.—Wanted the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9088.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9092.—Wanted, the address of firms manufacturing small beer brewing plants, from 75 to 100 gallons a day.

Inquiry No. 9094.—Wanted address of The Thomas Arithmometer Company, also Burkhart Arithmometer Company.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted address of makers of impulse water wheels.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9107.—Wanted, addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9113.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9115.—Wanted a machine for making pen nibs, similar to Wm. Mitchell's G & J nibs and Waverly nibs.

Inquiry No. 9118.—Wanted, a muffler for a gasoline engine, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9120.—Wanted, the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted, manufacturers of cut stencils for fancy work, sofa pillows, etc. and oil colors and brushes for same.

Inquiry No. 9124.—Wanted name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9127.—Wanted, address of L. Dermigny, manufacturer of a family ice machine for $12.50.

Inquiry No. 9134.—Wanted, a small hydraulic motor, capable of giving about one horse power with a water power of 85 lbs. per square inch.

Inquiry No. 9135.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted, a device that will braid leather strips for horse whips.

Inquiry No. 9138.—Wanted the address of manufacturers of machines capable of forming a number (12 or more) of pieces of paste about 35 mm. x 35 mm. x 4 mm. made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139.—Wanted, the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted, manufacturers of disc records for gramophones that use a sapphire point instead of a steel needle.

Inquiry No. 9143.—Wanted name and address of the manufacturers of an air mattress.

Inquiry No. 9144.—Wanted manufacturers of machinery for making soda water tubes, commonly known as straws.

Inquiry No. 9145.—Wanted, to buy machinery to [illegible]

Inquiry No. 9149.—Wanted, [illegible] machinery for [illegible]

Inquiry No. 9150.—Wanted [illegible] machinery for the manufacture of [illegible] shoes.

Inquiry No. 9152.—Wanted, the address of the Graham Safety Lamp Filler and [illegible].

Inquiry No. 9153.—Wanted, name and address of manufacturers of a [illegible].

Inquiry No. 9155.—Wanted, the address of manufacturers of an electric [illegible] machine.

Inquiry No. 9157.—Wanted, manufacturers of peanut [illegible] machinery.

Inquiry No. 9161.—Wanted, a machine that will grind oranges, pulp and skin into a smooth liquid or cream.

Inquiry No. 9162.—Wanted, addresses of shirt makers in Manhattan, who will make a few shirts of special design.

Inquiry No. 9163.—Wanted, manufacturers of a cradle worked by clock work.

Inquiry No. 9164.—Wanted, manufacturers of a vacuum pump that will exhaust from 20 to 25 [illegible] inches of air per stroke and built as light as possible.

Inquiry No. 9165.—Wanted, address of parties having deposits of colored glass sand or colored rock that is being crushed into sand.

Inquiry No. 9166.—Wanted, the address of O. [illegible] Street Sweeper and O. H. Butler Contracting Co.

Inquiry No. 9167.—Wanted, the address of the German Quartz Co.

Inquiry No. 9168.—Wanted, the name of manufacturer making the [illegible] Spring Terminal, sometimes called spring clip.

(Continued from page 500.)

Wright biplane before, it is safe to surmise that his cross-channel flyer was one of the new, powerful French Wrights, with a double horizontal rudder (a surface in the rear added, which as in the Farman machines, acts in unison with the front rudder). This is in accord with the Wrights' tendency to increase the power of the controls to the highest possible pitch, and at the same time it acts somewhat like an automatic steadying device. Any surface in the rear tends to steady.

In practical results Curtiss's flight may be said to have been the most fruitful of the three. This is due to its entirely unprecedented sustained speed over [illegible] long dist[illegible] ture that [illegible] Curtiss [illegible] In do[illegible] before [illegible] be de[illegible] A [illegible] suffici[illegible] with [illegible] super[illegible] for [illegible] chine [illegible] tor w[illegible] he had [illegible] so ha[illegible] cycle [illegible]

What [illegible] simply [illegible] plane [illegible] it is an [illegible] ful tra[illegible] of war, [illegible] short period of calm is rarely difficult to find, but that during such a period a Curtiss machine with its capacity for very high, sustained speed, may render services of the greatest practical usefulness. To many a business man it might be highly desirable if he could cover a distance like that from New York to Albany, between places where there is no direct railroad connection, with a speed exceeding that of the fastest express train, with comparatively slight expense and whenever half a day's calm weather can be counted upon. In war, the Curtiss type of machine may become a decisive factor in spite of its comparatively small carrying capacity.

Calm weather may be dreaded like the plague by the commanders-in-chief of future campaigns. The small, speedy Curtiss machines may be as immune from attacks from the ground as mosquitoes in the air. They may not only scent but also paralyze operations, not by throwing dynamite (their small supply would be exhausted before any great damage was done), but by setting things afire with the smallest quantities of burning chemicals—a modern revival of the Greek fire. These machines cannot be kept out of any part of the country they may choose to lay waste to. All this emphasizes how each step ahead in the conquest of the air demonstrates all the more clearly the dependence of the air pilot on the highest development of meteorological science.

## THE TEMPERATURE OF THE STARS.

(Continued from page 501.)

much higher than the temperature of the electric arc (3660 deg. C., or 6512 deg. F.) and agrees very well with the values obtained for the temperature of the sun, by actinometric or pyrheliometric methods, by Wilson (5773 deg. C., or 10.403 deg. F.) Scheiner (6200 deg C, or 11,192 deg F.), and Féry and Millochau (5360 deg. C., or 9680 deg. F)

The following table contains some of Nordmann's determinations of the temperatures of stars.

| NAME OF STAR. | TEMPERATURE. DEG C. | DEG F |
|---|---|---|
| Rho Persei | 2870 | 5200 |
| Beta Cephei | 4260 | 7700 |
| Gamma Cygni | 5620 | 10150 |
| Chi Herculis | 7350 | 13250 |
| Polaris | 8200 | 14800 |
| Alpha Lyrae | 12200 | 22000 |
| Alpha Persei | 13300 | 24000 |
| Gamma Lyrae | 14500 | 26100 |
| Epsilon Persei | 15200 | 27400 |
| Delta Persei | 18500 | 33300 |
| Lambda Tauri | 40000 | 72000 |

Independently of these thermal measurements, Nordmann's method, in connection with the spectral analysis of stars, gives information concerning their comparative stages of development. These very high temperatures explain the fact that in some of the stars the spectroscope reveals the existence only of elements like hydrogen, nitrogen and carbon, and the compound of carbon and nitrogen called cyanogen, which is in dissociable by heat.

Nordmann's apparatus also opens many new prospects in photometry, a science which is still in its infancy, except as regards the sun, although the exact measurement of stellar radiations, like that of stellar positions, is an indispensable prerequisite to the knowledge of the constitution of the stellar universe

The observations made at Harvard University and at Potsdam, Germany, in connection with the publication of the great photometric star catalogues, have begun to blaze the path, which astronomers have thought less difficult to follow than it really is In determining stellar magnitudes, the American and German observers merely measured with the photometer the total luminosity of each star, but, as the stars are of different colors, the values thus obtained are affected by errors of physiological origin Furthermore, it has long been known that estimations of the brightness of variable stars, especially red stars, exhibit great individual differences A comparison of the catalogues of Harvard and Potsdam shows differences in the recorded brightness of red stars If in one catalogue the ratio of the brightness of a red star to that of a white star is represented by E, it will be represented in the other catalogue by 3/2E. These systematic differences appear to be due to two distinct causes. The first source of error is purely physiological and consists in the fact that sensations of color are produced by the excitation of the terminal filaments of the optic nerve, which line the retina, and which are of three different sorts, sensitive respectively, and almost exclusively, to rays of the red, the green, and the blue and violet portions of the spectrum. Now this relative sensitiveness varies greatly in different individuals, as is strikingly illustrated by the extreme and pathological case of Daltonism, or color blindness. The luminous sensation produced by a given star, that is to say, the aggregate effect, impressed upon the filaments of the three different kinds, differs in different individuals. The second cause of error is found, apparently, in the phenomenon discovered by Purkinje, which may be expressed as follows: If two sources of light, one blue and the other red, appear equally bright to the eye, and if the brightness of each source is then diminished in the same proportion, the red light will appear less bright than the blue. The result is that, for the same observer, the estimation of the color of a star depends, other things being equal, upon the magnitude of the star and the aperture of the telescope Additional complications are introduced by the age of the astronomer, the position of his eye in respect to the eye piece, the degree of ocular fatigue, etc Fortunately, Nordmann's photometric method eliminates these errors in the determination of the total luminosity of stars. It makes possible an exact study of the colors of stars and of the dispersion of light in interstellar space Finally, it will undoubtedly give information concerning the intrinsic mechanism of the strange and mysterious transformations of variable stars of all classes

### A Storm-Warning Service for Aeronauts.

Dr Franz Linke director of the Meteorological Institute of the Physikalischer Verein at Frankfort-on the Main, has published a report on the special storm-warning service that he organized last summer in connection with the International Aeronautical Exposition This service, being the first of its kind, was experimental, but proved so successful that a similar undertaking is likely to be a feature of all future aeronautical competitions on a large scale, especially if held in a region of frequent thunderstorms

The prediction of large general storms can be safely left to the national weather services that now exist in all civilized countries Local storms, however, and especially thunderstorms, are notoriously difficult to forecast on the basis of the widely scattered reports that make up the ordinary weather map and that are all that the forecaster ordinarily has at his command The attention of the Frankfort service was directed especially to the prediction of thunderstorms The life history of these storms is now well understood thanks to the brilliant investigations of a small group of meteorologists of whom M Durand-Gréville is the most conspicuous In the great majority of cases they sweep across the country in a long line that may be compared to the front of an advancing army—the "thunderstorm front"—at a speed averaging, in Europe, about 40 kilometers an hour The line of advance keeps a position more or less parallel to itself, and its progress is not difficult to predict, if its existence and position are known at any given time The prerequisites of successful thunderstorm prediction are a dense network of reporting stations and a system of adequate telegraphic communication with the central station

Dr Linke engaged the services of fifty five observers constituting a picket line of 150 kilometers radius around the city of Frankfort These were mainly recruited from among the volunteer observers already reporting, but not by telegraph, to the existing meteorological institutes of Southern Germany These persons were requested to send an 'urgent' telegram to Frankfort whenever a thunderstorm or a wind-squall (which is first-cousin to the thunderstorm) appeared in their vicinity between the hours of 7 A M and 7 P M The compensation offered was a free entrance ticket to the exposition and a copy of the published results of the experiment

The result of these arrangements was most gratifying, as, with one or two exceptions, all the thirty-seven thunderstorms that reached Frankfort during the three months of the exposition were duly heralded an hour or more before their arrival

It is noted that no aircraft attempted to fly in the face of providence—and the weather forecaster—except the big Zeppelin," which began its famous voyage to Cologne against the advice of the forecaster and promptly ran into a heavy thunderstorm.

The entire cost of the service was only 600 marks ($150), an insignificant amount compared to the value of a single large airship, to which, as well as to the lives of aeronauts, an effective storm-warning service accordingly offers a cheap form of insurance

# SCIENTIFIC AMERICAN

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## THE OPEN DOOR OF AVIATION

In dissolving the injunction granted in favor of the Wright brothers against Curtiss, by Judge Hazel and the similar injunction granted by Judge Hand against Paulhan, the Circuit Court of Appeals has simply followed a long-established precedent in patent law. As a general rule, preliminary injunctions are not countenanced in patent cases even by lower tribunals. The reason is not far to seek. Rarely indeed is infringement so clearly established that a court is justified in restraining the manufacture and use of an invention before the question of patent validity is decided. The practice is in every way commendable. If preliminary injunctions were granted without entering into the question of validity, many an honest defendant's business would be crippled until, after years of litigation, his legal rights are clearly defined.

The hardship which results from too great a readiness on the part of a lower court to restrain an alleged infringer is excellently illustrated by this very injunction which the Wrights obtained against Curtiss and Paulhan. As a result of the interlocutory decrees of Judges Hand and Hazel the Wright brothers have controlled flying in this country for the last six months. Unless he filed a bond with the court, no aviator who used a machine equipped with ailerons or wing warping devices operated in conjunction with a vertical rudder could make, sell or fly his apparatus in this country. It is far from our intention to censure the Wright brothers for the attitude which they have taken. They are in every way justified in seeking to uphold their patents and in defending rights which unestablished as they are as yet from a legal point of view are nevertheless the fruit of painstaking experiments extending over years. Probably the counsel of the Wright brothers themselves were as much astonished by the willingness of Judges Hand and Hazel to grant injunctions against Curtiss and Paulhan as the patent profession at large. Curtiss at least was a successful aviator before the Wright brothers decided to cast aside all secrecy and to show the world what manner of machine was that of whose performances they had darkly hinted. Blériot, too, had been pluckily experimenting for some time before the Wrights flew in public. Curtiss was using hinged wing tips in his earlier machines with which he made public flights antedating the open flights of the Wrights. It is astonishing that the lower court should have failed to find in these facts a sufficient conflict of evidence to deny the granting of an injunction.

With the reversal of the decision of the lower court by the Circuit Court of Appeals, the development of aviation in this country is now unhampered. Paulhan, Sommer, Blériot, De Lesseps, and the rest of that daring company of French aerial pilots, whose exploits enliven the press dispatches almost every day, are now at liberty to enter this country and fly without the fear of finding their hands and their machines tied by a sweeping injunction. Moreover, American inventors will have the opportunity of improving existing machines provided with wing warping devices, without fear of incurring a fine for contempt of court. Much as we should like to see justice done to the Wrights, we cannot but feel that the reversal of an injunction granted contrary to established precedents will be viewed with satisfaction by every aeronaut.

## THE SCIENTIFIC AMERICAN AERONAUTICAL TROPHY.

Apart from the value which will attach to the Scientific American aeronautical trophy as indicating that its permanent owner has in three different years made the longest flight in the United States, the trophy will possess a strong historical and sentimental interest as being absolutely the first prize of any kind offered in America for the encouragement of the art of aviation.

In this respect the trophy must forever be unique among the countless cups and prizes which will be offered in increasing numbers during the years to come. Cups which are won year by year for certain special events and pass into the permanent ownership of the winner possess a value and interest which, however great at the time, must necessarily become local and personal as the years go by, but a trophy which carries the distinction of being the first to be offered in that early period of doubt and struggle which marks the inception of a great and difficult art such as that of flight through the air must ever possess a value all its own, which will inevitably increase with the lapse of time.

In this connection, we wish to draw the attention of entrants for the forthcoming long-distance, cross-country flights, for which such generous prizes have been offered, to the fact that upon their sending a letter of notification to the Aero Club of America their flights will receive official recognition, and if the distance covered should be greater than the seventy to seventy-five miles (official distance now under consideration) flown by Mr. Curtiss between Albany and Poughkeepsie, that contestant, unless his record should be surpassed before the close of the year, will be the winner of the cup for the year 1910. There is no entrance fee or expense of any kind attached to such an entry, the sending of a letter similar to that by Mr. Curtiss which was published in the Scientific American of June 11th, 1910, being all that is necessary.

We wish, moreover, to take this opportunity of correcting the rather widespread impression that the cup must be won three years in succession. As a matter of fact there is no stipulation of this character laid down. If a contestant wins the cup three times he becomes the [illegible], whether it is won in suc[illegible]considerable int[illegible] name is [illegible] and 1[illegible]r 1910, b[illegible]er con[illegible]beaten a[illegible]cribed [illegible]es in [illegible] perma-[illegible]try be fo[illegible]a and [illegible] would [illegible]he cup [illegible]s prize [illegible] are in [illegible] of the [illegible] are in [illegible]at the entrants for [illegible]he contest marked by the keenest rivalry.

## THE INTERNATIONAL UNION FOR CO-OPERATION IN SOLAR RESEARCH

If a scientific critic were called upon to mention one of the most striking and important features of modern astronomical research it is quite likely that he would refer to the spirit of organized and practical coöperation which is manifested by observatories and astronomers. By evolving suitable plans for joint efforts to enable each institution to do the work for which by equipment and position it is best suited, and by assigning through common agreement the particular part to be played in any given campaign, increased efficiency is secured, useless duplication is prevented and the entire project under prosecution can be advanced symmetrically and rapidly. The photographic charting of the heavens, the observation of transits and total solar eclipses, the study of the variation of latitude, and the investigation of the shape and mass of the earth, are a few familiar instances of valuable coöperative effort by astronomers.

More recently there has been an attempt to secure a similar harmony of effort and coöperation in the study of the sun, and in 1904 at the initiative of Prof. George E. Hale, director of the Mount Wilson Solar Observatory of the Carnegie Institution of Washington, there was formed among the visiting astronomers at the St. Louis Exposition an International Union for Coöperation in Solar Research. In the following year this Union met at Oxford, and in 1907 at the observatory of Meudon in France. This year, on August 29th, the members of the International Union will assemble at Mount Wilson, California, as the guests of Prof. Hale and the Solar Observatory of the Carnegie Institution. This meeting should prove unique and memorable, for it may be doubted whether there have ever been assembled so many eminent astronomers and astrophysicists interested in solar studies as those who have accepted the invitation for the Mount Wilson conference. That such a gathering is largely an appreciation of the important services to astronomical science of Prof. Hale and the observatory under his direction will be generally admitted, but at the same time these distinguished astronomers and physicists will be able to examine for themselves this interesting institution and its novel and powerful instruments by means of which several new chapters in our knowledge of solar phenomena have been written and still other discoveries, especially in the field of stellar evolution, seem destined to follow.

To most of the visiting scientists who never before have made the pilgrimage from Pasadena up the slopes of Mount Wilson the work of the Solar Observatory is familiar from accounts published in scientific periodicals. No one is more welcome before European astronomical societies than its distinguished director, who whenever abroad is always called upon to describe its progress. Therefore, it is not surprising that when the opportunity was afforded, some fifty representatives of important astronomical observatories and physical laboratories should decide to cross the Atlantic Ocean and the American continent to see and learn at first hand of work in which they are intimately interested. While it is a source of intense gratification to Americans that the Mount Wilson Observatory has become so pre-eminent in the brief space of some six years, yet it must be remembered that solar astronomy and astrophysics are prosecuted with vigor at other institutions and by numerous astronomers. It is this circumstance that makes of importance the coming meeting of the International Union.

The value of solar work may be appreciated when it is stated that the dry season at Kodaikanal in Southern India, where there is maintained a large observatory, corresponds with the rainy season at Mount Wilson, when of course the regular daily photographing of the sun is out of the question. With proper arrangements, therefore, it is possible to obtain a continuous photographic record of solar phenomena from one station or another on the earth's surface. Likewise the visual observation of the sun-spot spectra is definitely apportioned among various observers, so that each group receives a portion of the spectrum for thorough study, the results of the various observations being recorded on a common plan. Again, so important in modern solar research has become the use of spectroheliograph whereby the sun's surface or limb is photographed in light of a single wave-length, according to certain definite arrangements, that there is now an important chain of observatories from India across Europe and America to the Pacific Coast, where these instruments are in daily use. To record the amount of the sun's radiation received at the earth's surface, bolometers and other heat measuring devices are employed at various stations and continuous records are kept. In many cases it is quite obvious that local conditions may affect the observations and the records. Accordingly there must be simultaneous observations at a number of stations extending over as long periods of time as possible. These are being secured with ever greater efficiency by the members of the International Union for Coöperation in Solar Research. Such coöperative action is not intended to destroy initiative or originality in any observatory or astronomer, but rather to encourage it. To-day a large number of observers are engaged actively in solar research, and in no department of astronomy is a greater amount of progress being made. This is all the more striking as it was only a few years ago, to use Dr. E. E. Barnard's picturesque expression, that "the sun had almost been relegated to that limbo from which nothing new can ever come."

---

Some interesting communications relating to the general study of the earth were presented to the International Geodetic Association, which met in London in September, 1909. The values of the oblateness and the equatorial diameter which have been deduced from the triangulation established by the U. S. Coast and Geodetic Survey agree closely with the values obtained from European surveys. Prof. Eotvos exhibited a torsion balance which registers variations of the force of gravity more rapidly than the pendulum, and with equal accuracy. The experiments made by Dr. Hecker in the Indian Ocean confirm the generality of isostasis, i. e., increased density of the crust of the earth beneath depressions of the surface. Major Coningham has discovered one belt of more than normal density, lying beneath the Himalayas, and a second parallel belt south of that range. Hecker has also succeeded in protecting a horizontal pendulum from temperature variations sufficiently to detect an exceedingly small variation in gravity, having a period equal to one-half of a lunar day. The variation attains two-thirds of its theoretical amplitude and gives the earth, as a whole, a rigidity comparable with that of steel. The resistance to deformation is greater in an east and west than in a north and south direction. This difference is probably caused by the earth's rotation.

## ENGINEERING.

[illegible] government had placed a submarine [illegible] off the Lizard. It is suspended from a heavy [illegible], which was lowered to the bed of the ocean [illegible] a point about two miles from land. The bell is connected by cable with the lighthouse, from which it will be operated. It is anticipated that, since steamers [illegible] up the Channel all approach the Lizard, the bell will be of great assistance to them, particularly in time of fog.

Very gratifying is the steady growth in efficiency of the successive submarines which are being tried out for the United States navy The "Salmon," built at the Fore River yards and designed for 11 knots at the surface and 10 knots submerged, established last month a surface record of 13¼ knots, and a record below the surface of 12 3/10 knots. Four torpedoes, discharged when the ship was at full speed in the submerged condition, scored what was practically a series of bulls-eyes.

It is reported by the Engineering Agency of South Africa, Johannesburg, that an important body of iron ore has been found in Natal, within thirty miles of the railway and within seventy five miles of the coast. Limestone has been located in large quantities at a distance of only a mile from the ore body, and coking coal has also been discovered in Natal In view of the fact that the River Tegela, which is suitable for the development of hydro-electric power, runs through the iron ore property, it is likely that the new find will be turned to immediate commercial account.

The removal of the twelve-year-old, 20-story Gillender Building at Wall and Nassau Streets in this city is certainly a record in house-wrecking. The time allowed was 45 days at a price of $50,000, with a penalty of $500 for every day exceeding that period. The work will be done within the specified time. The most difficult work has been the removal of the brick backing of the outside stone work The steel frame was taken down, piece by piece, by knocking off the heads of the rivets and driving the latter out with a drift pin The steel work will be available for other construction.

The system of transmitting train orders in this country by the telephone is making rapid strides Statistics filed by the Interstate Commerce Commission show that the telephone is being used for this purpose on 295 roads in the United States, on which 26,244 miles of road are operated by this method On ten of the roads telephone dispatching covers 500 miles or more, and on five roads the distance covered exceeds 1,000 miles, this being the case on the Atchison, Topeka & Santa Fé, the Chicago, Burlington & Quincy, the Great Northern, the Illinois Central, and the Pennsylvania Railroad.

The Bergen tunnel under Jersey City Heights, through which for forty years all passenger trains on the Erie Railroad have been run, will be abandoned on July 1st for passenger service, and will be given over wholly to the movement of freight. After that date passenger trains will make use of a great open-air four-track cut, upon which the contractors have been at work for the past three years The cut, which extends for 4,400 feet through the Heights, is 58 feet wide at the bottom, and varies from 45 to 85 feet in depth. It is intersected by four tunnels, where the material has been left in place to carry the streets above, but none of these is of greater length than an ordinary train

In a recent fire test of the reinforced concrete floor of a tall building, the following excellent results were obtained. The floor panels measured 22 feet by 20 feet, center to center of the columns, and they were required to stand a test load of 200 pounds per square foot with a deflection not above three-quarters of an inch. In the test, the deflection under this load was only one-eighth of an inch With a hot fire beneath the floor, there was an increased deflection of 1⅛ inches. Water from a fire hose was then directed against the bottom of the now heated concrete, when the floor rose seven-eighths of an inch, leaving one and one-quarter of an inch deflection. This test, it should be understood, was made of a floor in the completed building.

The New York, New Haven and Hartford Railroad have received from the Westinghouse Company a new single-phase electric locomotive for the high-speed passenger service between New York and Stamford, which is of double the capacity of those already in service on the New Haven road. The specifications called for a locomotive which could haul a 1,500-ton freight train at a speed of 35 miles an hour on level track, where the train resistance was not more than 6 pounds per ton. The locomotive was also to be capable of hauling an 800-ton passenger train at a speed of 45 miles per hour. In the tests, it [illegible] a heavy freight [illegible] and a caboose, were [illegible] New Rochelle to Stamford, a distance of [illegible] the maximum speed attained [illegible].

## ELECTRICITY.

It has been proposed that the surplus water from the canal locks at Lockport be utilized to generate current which may be employed in lighting the Erie Canal from the Tonawandas to Albion Surely the advantages such a system would offer would well repay the cost of installation and maintenance.

An electric cable has been laid in Oneida Lake connecting Frenchman's Island with the mainland The distance is a little over a mile. The cable is to conduct current at 6,600 volts to the island, where it will be stepped down to 110 volts to be used for lighting the pavilions and amusement apparatus of the resort. This is said to be the first long-distance, high-tension submarine cable ever laid

The United States Senate has passed the bill introduced by Senator Depew governing wireless telegraphy It requires that all wireless stations secure licenses from the Department of Commerce and Labor The bill aims to prevent interference of messages and the sending of false distress signals and gives the army and navy messages the priority over commercial messages.

For some years wireless telegraph experiments have been conducted by Dr Frederick H Millener for the Union Pacific Railroad It is stated that the road is soon to establish a wireless telegraph system of communication with moving trains. Tall towers are to be erected at Sydney and Cheyenne, which will have a wide radius of communication. The system should be invaluable in the case of the interruption of wire service by storms.

Illustrative of the rapid improvement in metal lamp filaments is the recent decision of the Chicago Railway Company to install tantalum lamps on all new cars and cars that have to be rebuilt Before arriving at this decision, a series of tests was conducted, extending over a period of six months. Lamps were installed on cars in regular service and accurate records were kept which demonstrated their efficiency for this class of [illegible]

The [illegible] pointed a [illegible] [illegible] voltage [illegible] large [illegible] the danger of a [illegible] short circuiting of high potential lines would be greater than the chance of a shock from secondary of 240 to 300 volts. For this reason, the recommendation regarding circuits of more than 150 volts was withdrawn

Now that the thunder storm season is here, the Denver City Tramway Company is instructing its employes in the safest method of running their cars during a storm. The motormen are ordered to let the cars coast as much as possible, so that in case of being struck by lightning, the vital apparatus of the car would not be so liable to injury The motormen are also instructed to note, if possible, the position of the controller handle when the car is struck by lightning. If the current were off, the injury would probably be confined to the controller box. Otherwise it might damage the motors, or it might burn off the trolley wire at the base of the trolley pole. In the latter event, it would be necessary to have the car pushed back to the barns.

Paris time was transmitted some days ago from the Eiffel Tower by wireless telegraphy to all wireless stations and ships fitted with wireless apparatus within a radius of 2,500 and 3,000 miles. The time signals are to be continued and will be sent at midnight, and again at two minutes and four minutes after. The receipt of a signal will not enable a ship to determine its position or even its longitude, but will serve as a check on the chronometer. This test of wireless signaling for time at sea has brought up the question of the kind of error, in longitude, to which in these days of accurate navigation a ship is liable An error accumulates with the time at sea and as all ships carry at least three chronometers, there should not after a lapse of 100 days be the least doubt of a ship's longitude—that is within a few seconds—but the number of time signals scattered over the world is now so large that every steamer has the opportunity of correcting its own chronometers more frequently than is here suggested.

## SCIENCE.

Prof. E. E. Barnard informs us that on June 6th he obtained a very good photograph of Halley's comet. The plate showed the tail drifting off into space, and a new one forming in a different direction

The collection of fresh-water sponges of the U S National Museum is now being critically examined by Dr Nelson Annandale, superintendent of the Indian Museum in Calcutta, who is an accepted authority on this subject. Under the title of "Description of a New Species of Spongilla from China" there has just been issued paper No. 1737 of the Proceedings of the U S National Museum In this publication Dr Annandale describes as new *Spongilla (Stratospongilla) sinensis* which appears to be allied to *Spongilla aspinosa* Potts from which however it differs in its compact structure and lack of flesh spicules This specimen was found on rocks in the canal in southern Kiang Su, near Shanghai, China The type is in the collection of the U S National Museum

Prof. Negro of the University of Boulogne, has studied the radio-activity of dew The precipitation was made on glass plates exposed in immediate contact with the soil for several hours, beginning at about eight o'clock in the evening It is interesting to note that the water vapor was deposited entirely on the surface turned toward the ground while the opposite surface was quite free from any trace of moisture. From Negro's experiments it would seem that, as in the case of snow and rain, the activity of dew disappears almost entirely in a very short time, which may be placed at not much more than half an hour The maximum radio-activity is detected not immediately after the introduction of the plates into an electro-static apparatus, but some minutes afterwards, in which respect it differs from snow and rain

In one of the Leopoldshall workings a blower of inflammable gas has been issuing at a depth of 1,500 feet, since August, 1904 The gas contains 83 6 per cent of hydrogen, 4 4 per cent of methane and 12 of other gases including neon and helium The helium greatly preponderates over the neon but the two together form about 0 17 per cent of the original gas, or nearly 1 per cent of the gas after removal of the hydrogen The German chemist E Erdmann has investigated this gas and he calculates that at least 12 cubic meters of the above gases have escaped since the blower was tapped He attributes the existence of the helium to the degradation of radium salts originally contained in the waters of the sea which furnished the deposits, and he regards the hydrogen as resulting from the radio-active decomposition of water, the equivalent oxygen having disappeared in converting ferrous into ferric salts in the carnallite

Mr. Austin Hobart Clark, an accepted authority on crinoids, has recently published two papers in the Proceedings of the U S National Museum The first of these papers, No 1740, is "On the Origin of Certain Types of Crinoid Stems" and in which he discusses the probable relationship between the column of the crinoid and the central or sur-anal plate of the echinoid, and how widely different types of columns may be reduced logically to a primitive common ancestor Among his conclusions from the evidence he presents is that the stems of the recent and most of the fossil crinoids may be derived by supposing them to be the homologue of the central plate of the crinoid echinoid ancestor which has gradually become thickened and elongated and developed transverse alternating fractures which have metamorphosed into definite articulations. The second paper No 1743 bearing the title "A New Australian Crinoid," is a description of a new species which he calls *Compsometra loccrtosa* and which was obtained at Port Jackson, New South Wales, by Mr J Bracebridge Wilson in the summer of 1887-88

The late Prof Garriott, of the U S Weather Bureau, was working at the time of his recent sudden death on a very promising method of long range forecasting, based on the observation of departures from normal pressure in widely separated regions of the world Telegraphic reports of the pressure at European and Asiatic stations are received every morning in Washington, and were utilized for this purpose The study of "correlative meteorology"—i e, the interrelations of atmospheric phenomena in parts of the world far remote from one another—is now occupying the serious attention of meteorologists in all countries, and is one of the two salient features in the recent development of their science, the other being the exploration of the atmosphere by means of kites and balloons. An international commission was recently organized, under the presidency of M Léon Teisserenc de Bort for the purpose of maintaining a world-wide telegraphic interchange of meteorological observations, so that in the future, if the plans of the commission can be realized, the forecaster will have at his disposal a daily weather map embracing the whole world, instead of a single country.

# MODERN STEEL LOCK BAR PIPE CONSTRUCTION

BY FRANK C. PERKINS

In considering the use of steel pipe as compared with cast iron pipe, it should be remembered that the value of water pipe depends on carrying capacity, strength and durability as well as cost The accompanying illustration Fig 1, shows 48 inch lock bar pipe lying in a trench at Philadelphia, Pa., while the details of construction are noted in Fig 2 It is held that the cost is about 5 per cent more than riveted pipe, but it has greater strength and carrying capacity

It may be stated that this capacity depends on friction, and riveted pipe presents an obstruction at every rivet and every circular and longitudinal seam.

It is also claimed that the uniform section of the lock bar pipe without any obstruction of any kind from end to end of each length of pipe, materially reduces friction Some engineers say the carrying capacity of lock bar pipe is from 10 to 15 per cent greater than riveted pipe or is equal to well-coated, well laid iron pipe

Tests on 30 inch pipe at Lockport, N Y, in 1909, showed a friction loss less than that given by Watson's Tables for cast-iron pipe It is well known that steel pipe is materially stronger than cast iron pipe During a cloudburst in 1903, two 48 inch riveted steel pipe lines carrying 50,000,000 gallons per day for Newark, N J, were undermined and left unsupported for four days for over 25 feet, and in addition to the weight of the pipe and the water passing through them (about 15 tons), there were some thirty uprooted trees piled up over the pipe which supported this immense weight and pressure, without damage.

It is conceded that cast iron is brittle and treacherous at best and though apparently sound one day, may prove defective the next, and break without a moment's notice

It is of course true that the strength of any steel pipe is equal to the strength of the joints. Single riveted joints have an efficiency of about 55 per cent, double riveted joints about 65 per cent, triple riveted double, buttstrap joints about 86 per cent, and welded joints about 90 per cent. Lock bar joints have an efficiency of 100 per cent, and have greater strength than plates themselves, as all tests result in a failure of the plate, without injury to the joint. A 42-inch diameter 7/16-inch plate lock bar pipe was tested to 1,050 pounds pressure, and the metal of the plate was stretched 4½ inches with neither injury to the lock bar joint nor the least leakage along the same. Further pressure was impossible, because of the blowing out of the riveted reinforcing pads at the inlet and the gage.

It is maintained that lock bar pipe is from 20 to 30 per cent stronger than riveted pipe and 10 per cent stronger than welded pipe, and experience has shown that the natural life of steel pipe when properly made and laid is fully equal to that of cast-iron pipe.

Without doubt the life of all metal is less than it was twenty years ago, as nowadays electrolysis, sulphurous acid, galvanic action and other agents greatly accelerate corrosion. It is therefore most difficult to compare the life of pipe laid within the last twenty years and pipe laid prior to that time, because of these constantly increasing corrosive influences.

Before closing. After closing.

---

According to experiments on the reception of radio-telegraphic signals when transmitting with a spark gap in compressed air, as compared with signals received when an ordinary spark gap was used, there appears to be no advantage in using compressed air for this purpose. While the dielectric strength of the air is enormously increased, so also is the resistance to the oscillatory spark, both appearing to increase in about the same ratio.

# THE WEARING QU[illegible]NGANESE STEEL

Manganese steel is by no means a new material, but its application has been slow because of the difficulties which manifest themselves in giving its final form It seems to have been discovered by Hadfield's Steel Foundry Company, Sheffield, England, some thirty or forty years ago, when seeking a hard and tough substitute for steel when used for castings It was found that the mere increase of carbon in the steel did not have the desired effect Steel having a carbon content as high as 2 per cent was unsuccessfully tried It was known that when the manganese content of a steel somewhat exceeded 2.75 per cent, the alloy would be brittle What was not known and what the Hadfield Company found out was that if the manganese were increased to a point ranging anywhere from 7 per cent to 20 per cent a steel might be produced which is remarkably strong and tough Now this reversal of a leading property of an alloy by merely increasing the proportion of one of its constituents is, as R A. Hadfield pointed out, not without precedent In forming alloys of copper and tin, the resultant alloys seem to become harder and more brittle as the tin content rises from a low point up to a considerable percentage say 25 per cent, but when more tin is present than the soft and tough copper, the alloy becomes softer

It was early found, however, that manganese steel was a very refractory metal to machine. The properties of hardness and toughness produced a combination that was very successful in resisting the cutting edge of the tool And this characteristic is, even today, a bar to the application of this metal We have high-speed steels capable of enormous performance when used against the pure carbon steels and cast iron. But manganese steels still hold out. Almost the only practicable thing to do is to use the grinder. Now the grinding machine is of late become a strong competitor of the ordinary machine tool. But its development has hardly been carried far enough to enable it to handle commercially the multiplicity of cutting operations necessary to enable manganese steel to have a general application to all the purposes for which it is highly adapted. Further, it has been found difficult to roll

But so great are the intrinsic capabilities of this material for certain uses that, in spite of the difficulties of giving it the desired form, it has been pretty rapidly acquiring friends. Consider, for example, the case of the Boston Elevated Railway Company This corporation operates its transportation system on a track [illegible] others have radii between 100 and 150 feet. Soon after operation began, those in charge became impressed with the fact that an enormous destruction of rails was taking place on the curves. This has been ascribed largely to the sharpness of the curves, and to the combination of grades and curves. It was on the curve of the Park Street south-bound track where the ordinary rail had a life of but about 44 days. The radius here is 82 feet. At the same locality, an open-hearth rail went out of service in even less time At Adams Square, where there is a curve of 89 feet radius, a low-carbon Bessemer, an open hearth, and a high-carbon Bessemer rail were all tried The last was the only one which had even a moderate life—10½ months. Nickel steel was tried on a 100-foot curve at Haverhill Street. But its life was less than that of a high-carbon Bessemer rail at the same location, the two periods being 6 months 19 days and 11 months 13 days. Apparently, however, better results were obtained from nickel steel than this instance would indicate, as Mr. Steward, the roadmaster, regards the nickel-steel rails as comparing well with ordinary steel. The company tried manganese-steel rails as well. In one case, a nickel-steel rail was put in between two manganese-steel rails, with the result that after the lapse of 204 days it had to be taken out because of its failure to equal its companions. The center of the head had been worn down over ½ inch, while the corresponding position on a manganese-steel rail disclosed a reduction of but 3/16 inch. But perhaps a more striking example is that of a manganese-steel rail at the Park Street station, where the wear was the same in a period over four times as long. In fact, a manganese-steel rail laid on April 26th, 1902, showed loss from the top surface amounting to only about 9/16 inch after the lapse of 2,40[illegible] days. The accompanying engraving shows the Park Street curve.

An examination of Figs. 4 and 5 will show, however, that the edge, where the transition surface from cone to flange acted, suffered considerably. In fact, the corporation now protects the manganese-steel rail from side friction by means of a guard rail. It is probable that some, perhaps a large, part of the wear from the flange has been prevented. At any rate, Mr. Steward has expressed his opinion that the manganese-steel rail will not resist the flange action nearly so well as that of the cone.

Now, it should be observed, the [illegible]

(Concluded on page [illegible].)

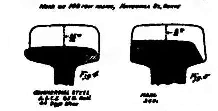

Diagram showing extraordinary wearing qualities of manganese steel rails.

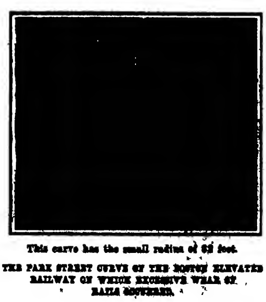


This curve has the small radius of 82 feet.

THE PARK STREET CURVE OF THE BOSTON ELEVATED RAILWAY ON WHICH EXCESSIVE WEAR OF RAILS OCCURRED.

# THE CONTAGIOUS DISEASES OF METALS

## THE RESEARCHES OF PROF. ERNEST COHEN

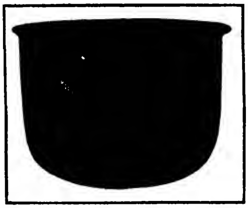
It has been known for some time, and probably even in antiquity, that metals are subject to diseased conditions. Prof. Ernest Cohen's researches have thrown considerable light on this question and have demonstrated, moreover, the contagious nature of such diseases, that is to say, a piece of diseased metal has the power of infecting, by a sort of catalytic action, a piece of sound metal with which it is in contact

### TIN PEST

In 1851 Erdmann, in a communication made to the Royal Society of Sciences at Leipsic, called attention to a peculiar structural modification of tin which he had observed in some old organ pipes. He attributed the change to the vibrations to which the metal had been subjected. In 1869 Fritzsche of St. Petersburg published observations of similar phenomena, and expressed the opinion that the alteration in the nature of the tin was due to the action of severe cold to which such tin had been exposed, and verified the correctness of this theory experimentally Other investigators turned their attention to this subject, but the true nature of the modification and the exact conditions governing its appearance and development were not fully understood until they were determined by Prof. Cohen.

The disease studied by Erdmann and Fritzsche is designated by Prof Cohen as tin pest. The metal thus affected swells in spots, forming wart like blisters, from which small drops issue and hang suspended in very much the same manner that drops of quicksilver will adhere to polished copper coins In the further progress of the disease, the blisters become larger and the metallic gloss disappears more and more The interior of the mass is affected last, as can be shown by sawing through the metal whose surface has become quite dull When the entire mass has been transformed, it crumbles readily, and consists partly of a granular powder similar to sand, and partly of more or less consistent fibrous lumps of all sizes up to that of a fist. When a piece of tin is cooled artificially, the modification appears first at isolated spots, from which it spreads in wart-like blisters and later forms a columnar structure

Tin thus modified by the action of cold is distinctly gray, the application of heat produces a remarkable change. Even by merely covering it with hot water, the dark gray color is caused to become materially lighter, approaching that of ordinary tin. The change is due to the temperature exclusively. If a specimen of powdery modified tin is heated in a closed vessel by means of a water bath, it not only assumes a lighter color but decreases in volume quite perceptibly. If it is then cooled again below the freezing point of mercury, it again becomes almost as dark as it was before heating If modified, tin is heated to fusion, an appreciable proportion will remain in the oxidized state The molten portion will upon solidification assume the appearance of ordinary tin, and if cooled to a low temperature, it can be transformed

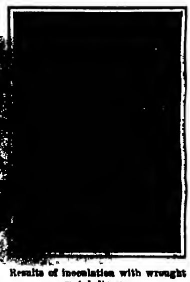


Brass kettle corroded by the wrought metal disease.

again into the gray modification Ordinary tin has a specific gravity of 7 28, but gray tin is considerably lighter, having a gravity of only 5 75

Prof Cohen directed his attention at first to determining the temperature at which ordinary tin is transformed into the gray modification, the results obtained by former investigators differing widely, some having found 35 deg (Centigrade) as the critical point, others 100 deg., etc Fritzsche's experiments indicating that the transformation was enantiotropic or reversible, it was to be expected that there would be a definite temperature at which the transformation might proceed in either direction

Antique coffee pot perforated by the tin disease.



Results of inoculation with wrought metal disease.

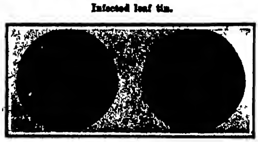
Prof Cohen employed two independent methods for determining this critical temperature One, an electrical method, consisted in bringing two separate bodies of gray tin into a vessel containing a 10 per cent solution of chlorostannate of ammonium The two bodies of tin are connected with an apparatus permitting the experimenter to observe and measure any electromotive force arising in the cell As long as both bodies are of the same temperature, there is no electromotive force. But if one of the tin bodies is given the temperature of boiling water, and the other that of cold water, the heated body is transformed into ordinary white tin, while the cooled body remains gray The electromotive force manifested under these conditions was measured at different temperatures At about 20 deg C the electromotive force was equal to zero, indicating that the critical temperature is in the neighborhood of 20 deg. C. Prof Cohen also found that the presence of the chlorostannate of ammonium solution accelerated the transformation considerably, in both directions

The other method was a volumetric one based on the fact, stated above, that the two forms of tin have different specific gravity The apparatus employed is very similar to an ordinary thermometer, except that the capillary tube is open at the top The lower part of the bulb is filled with gray tin, the upper part and a portion of the capillary tube with a liquid inert relatively to tin, such as petroleum The apparatus is heated to a temperature (say 25 deg C ) a few degrees above the probable critical point, so that a portion of the gray tin is transformed into the white variety Then the apparatus is kept for some time at a constant temperature of say 21 deg C and the behavior of the petroleum column is observed by means of the scale After a few minutes it will be found to have fallen a few millimeters thus indicating that 21 deg C is still above the critical temperature, for as long as the formation of white tin continues, the mass of tin contracts in volume, owing to the greater specific gravity of white tin The temperature being then kept constant for a time say at 15 deg C, observation will show a rise of the petroleum column, thus indicating that the volume of the tin has increased by the formation of the specifically lighter gray tin, so that the critical point must be above 15 deg C By successive operations a gradual approach to the critical point is obtained by working at temperatures alternately above and below said point, and when the limits have been restricted sufficiently, interpolation is resorted to This method also showed that the critical temperature must be in the neighborhood of 20 deg C, and careful determination proved it to be almost exactly 18 deg Centigrade (about 65 deg Fahrenheit)

Since all tin utensils employed by us are made of the white modification, it follows that they are gen-

A pig block of Banca tin three weeks after infection.

Infected leaf tin.



Metal infected by tin pest.

Infected sheet tin from Rotenburg City Hall.

erally in an nnstable co[illegible]n and liable to be transformed partly into the gray variety, except on days when the temperatnre exceeds 65 deg Fahrenheit.

The second method described above was also utilized to ascertain at what temperature the transformation of white tin into gray tin proceeds with the greatest rapidity and this was found to be the case at about 48 deg. Centigrade below zero (abont 54 deg F below zero)

An interesting discovery was that the transformation is hastened considerably by the presence of a few particles or "germs" of gray tin It follows that if an "infected" piece or object of white tin is left to itself at temperatnres below 65 deg. Fahrenheit, the transformation will proceed constantly and with increasing rapidity, for each particle of gray tin, as soon as it is formed, becomes a new germ accelerating the transformation Prof Cohen has given this phenomenon the name of tin pest in view of the germ like or infectious action of the gray tin particles, and also in view of the fact that the tin so attacked is practically ruined, since the restoration of tin by melting is attended with great losses owing to the strong oxidation which takes place during the heating, on account of the finely divided condition of the gray tin

The formation of blisters during the conversion of the tin into the gray variety is a natnral consequence of the increase of volume, since gray tin is about 25 per cent lighter than white tin

Tin articles which have been exposed to low temperatures for a long time, say several centuries, would naturally be expected to exhibit a maximum of deterioration This is indeed the case, as has been proved by the condition of antique tin vases, medals, and other objects dug up in our times In museums, too, the deterioration of tin articles has been observed frequently, but the cause was not understood and no remedy was known In the light of Prof Cohen's discoveries, the remedy is simple we have only to see to it that the articles are never exposed to a temperature below 18 deg Centigrade (65 deg Fahrenheit) Investigation has shown that in many cases where excessive and apparently unaccountable deterioration of tin articles had been reported, the articles had been exposed to low temperatures during the winter

WROUGHT METAL DISEASE

Strange phenomena were observed by R. von Hasslinger at the tinned solder seams of an air-compressor made of tinned sheet iron The solder had melted away in spots, as it were, and had assumed a crystalline structure, the tin covering of the sheet iron had become granular and dull on its entire surface. It was unlikely that the result was due to tin pest, since the compressor had seldom, if ever, been exposed to temperatures below 18 deg Centigrade R. von Hasslinger ascertained that pieces of this diseased tin would infect sound tin, and that this was apparently independent of the temperature thus indicating again that the form of tin pest previously recognized was not the cause of this newly observed transformation. The tin became crystallized in minute wart like bodies and the dull portion would spread gradually, but the rate of growth decreased with the increasing distance from the center of infection R. von Hasslinger thought that the phenomenon was due to crystallization, and continued his experiments, showing that the modified tin had a lower melting point than the original metal, about 205 deg Centigrade instead of 232 deg He also found that tin foil infected on one side would become modified on both sides Other experiments made by him, however, seemed to indicate that the crystallization theory was erroneous, and he published the result of his observations with an acknowledgment that he was unable to account for them An untimely death having prevented von Hasslinger from concluding his investigations, his teacher, Prof Guido Goldschmiedt, of Prague, drew Prof Cohen's attention to the unexplained phenomena and suggested that he continue the research

Prof Cohen repeated von Hasslinger's experiments and verified them in many ways He ascertained that the small lead contents of the tin would in no way be held responsible for the result. He first believed that the phenomena might be explained by the formation of the rhombic modification of tin which is unstable at temperatures below 161 deg C, having a tendency to resume the normal tetragonal form If this hypothesis had been correct, the phenomena should have been absent at temperatures of 161 deg. C. and above Experiments, however, showed that the transformation into the new dull powdery form of tin took place at 184 deg. C even more rapidly than at lower temperatnres. This hypothesis therefore had to be abandoned

Prof Cohen then turned to another explanation, based on two well-known facts First, that a metal which has been subjected to a tensile or to a compression strain (such metal being designated as "wrought metal" by Prof. Cohen) has an electrolytic solution pressure higher than the same metal if it has not been subjected to mechanical forces; second, that several metals, tin among others, have the property of recrystallization, that is, of exhibiting a growth of their individual crystal grains, more particularly at high temperatures.

It is well known that two specimens of "wrought metal" are seldom absolutely identical in an electrolytic sense, and "wrought metal" is in an unstable condition, having a tendency to return to the condition of "unwrought metal" This tendency, slight at ordinary temperatures, ought theoretically to be strengthened by an increase of temperature, within certain limits, and it is also to be expected that inoculation with the form most stable under the particular conditions of the case, would hasten the transformation These theoretical deductions have been fully confirmed by experiments.

Prof Cohen cleaned some plates of tinned sheet iron with hydrochloric acid and potassium chlorate. This produces, in a short time, the well-known metallic moiré effect. The surface is then washed carefully and rubbed with a fine handkerchief The plate so prepared is pressed in a vise against a highly polished plate of tinned sheet iron, and upon heating to 184 deg. C the polished plate becomes infected and acquires the property of infecting others If however both plates are highly polished, no modification will occur Another experiment consisted in applying to a moiré plate such as mentioned above, some powdered infected tin foil and on top of this, a polished plate of tinned sheet iron Heating to 100 deg. C caused the polished plate to be affected immediately, while the moiré plate remained unaltered even after 24 hours.

It follows that "wrought tin" (rolled tin, tinned sheet-iron tin foil) must be considered an unstable product, in process of recrystallization The form which is stable at ordinary temperature is the gray tin but the transformation is extremely slow at such temperatures. Within certain limits, an increase of temperature increases the rapidity of transformation Contact (inoculation) with the more stable form also accelerates the transformation appreciably. Tinned [illegible] under the particular conditions. Similar effects of corrosion were observed on brass door handles, and Prof. Cohen also thinks that "wrought metal disease" accounts for the peculiar deterioration of the rolled lead roof of a sulfuric acid factory The temperature of from 40 deg. C to 60 deg C., to which the roof had been exposed, was very favorable to the recrystallization process.

### The Current Supplement.

The opening article of the current SUPPLEMENT, No 1799, describes a saw-dust compressing machine.—Recent developments of American locomotives are discussed.—Mr Leon A Hackett's excellent article on the Processes in Cotton Spinning is concluded.—Prof. J A. Ewing reviews the work of Lord Kelvin in telegraphy and navigation.—In an excellent article entitled "Oil Field Phenomena," Mr A. Beeby Thompson gives a brief review of the mode of occurrence of petroleum and the means adopted for its search and recovery.—Mr R. T Hewlett writes on sonred milk from the Metchnikoff standpoint.—Plant anesthetics is explained by S Leonard Bastin

It is reported in the Electrician that the Chicago Elevated Railway Commission is considering five plans to solve the problem of "through routes" for elevated trains in that city Thirty-eight plans were submitted to the Commission, and five of these were selected for more careful study. Mr. B. J. Arnold, who is chairman of the Commission, feels that progress has been made in narrowing down the work. It is pointed out that each of the four elevated railway companies is operating under a separate ordinance granted by the city, and that the inter-relation of the elevated lines is caused by the joint use of the "down-town" Union loop. The companies are doubtful whether they can afford to haul passengers for a greater distance than about six miles for five cents, but there is apparently a desire on the part of everybody concerned to reach a solution of the question.

## [illegible]

### A CALL TO AMATEUR WIRELESS OPERATORS.

To the Editor of the SCIENTIFIC AMERICAN:

The amateurs and experimenters in wireless telegraphy in New York city and Philadelphia have started a movement to organize all the amateurs in America with a view of expressing to Congress the opinion of the organized amateurs as regards restrictive legislation. The amateurs desire that a full opportunity may be given them to express their views to Congress before any of the pending bills be enacted into law

I have been retained as counsel for this movement. If your valuable paper will publish this letter, I trust that every wireless enthusiast throughout the United States will send his name to me at my office, [illegible] Building, Washington, D. C.

GEO. HIRAM MANN.

### "MECHANIPULATE."

To the Editor of the SCIENTIFIC AMERICAN:

Relative to your suggestion, regarding the new word proposed by Mr. Wood, namely, "mechanipulate," it seems to me rather complicated, and I would suggest that the more homely term, machining or machined, would be far more appropriate in the application which he suggests. E. W MOCKING.

Waterbury, Conn.

[The term mechanipulate does not refer to the "machining" but to the mechanical handling, i. e., moving, placing, centering, etc., of a piece of work. —ED.]

### GIVING THE APPEARANCE OF RELIEF TO PICTURES.

To the Editor of the SCIENTIFIC AMERICAN:

A simple method of giving the appearance of relief to pictures can be seen by the experiment that if a sheet of glass with minute cylindrical fluting on a side held against a photograph, with the series of flutes vertical, be viewed through, the dispersing light gives the picture a stereographic effect of solidity.

The utility of a minutely fluted dispersing picture cover glass screen therefore can be shown, which is caused by the semicircle dispersion by the cylindrical flutes of the light that is reflected by the photograph. The determining factors are the minuteness of the fluting and the position and the thinness of the viewing screen

The dispersion of the light by the refraction through these adjoining flutes of this stereoscopic screen presents to each eye a different appropriate view of the picture, which produces the impression of solidity and depth. A. F WOOD CHENOWETH

London, England

### Scientific American Prizes for Inventors.

The SCIENTIFIC AMERICAN offers $100 in three prizes, to be awarded to the inventor who gives the best account of how he conceived his invention, how he developed it in actual practice, and how he succeeded in selling it. This sum of $100 to be distributed as follows $50 to the best account, $35 to the second best account, $15 to the third best account.

There is no limitation as to subject matter of the invention. In other words, the invention may be a household utensil, a game, a piece of electrical apparatus, an improvement in railway construction, a metallurgical process, etc The following conditions, however, must be observed

1 The invention must be patented.

2. The inventor must have actually sold his patent, and the invention must have been commercially introduced.

3 The account of the inventor's success must not be longer than 800 words.

4 The composition, letter, or article must be typewritten on one side of the paper only

5 The inventor must sign his offering with a pseudonym, and inclose it in a sealed envelope, upon which the pseudonym is written. A second sealed envelope must be provided, bearing on the outside the pseudonym under which the offering is submitted, and containing the real name and address of the contestant.

6 Contestants must address their offerings to Inventors' Prize Editor, SCIENTIFIC AMERICAN, [illegible] Broadway, New York city.

7. The contest remains open until [illegible] Judges will select the essays which, in their opinion, have won the three prizes and give them to the Editor of the SCIENTIFIC AMERICAN, who will [illegible] the sealed envelopes containing the [illegible] contestants, and notify the [illegible]

8. The Editor of the [illegible] right to publish [illegible] as well as those [illegible]

9. [illegible]

## [illegible] Independence Day Casualties.

[illegible]

[illegible] columns of the issue of July 3rd, 1909, [illegible] the title "Tetanus and the Glorious Fourth," I [illegible] data regarding the dreadful injuries and [illegible] suffered year after year by our children and [illegible] because of the methods with which for a century [illegible] more our people have been celebrating Independ[illegible] Day. I pointed out that the greatest danger lay [illegible] tetanus or lockjaw; and that most of the cases of "[illegible] of July tetanus" have come about through [illegible] of blank cartridges in toy pistols and of giant [illegible].

I dwelt upon the tetanus bacillus, the germ responsible for this disease, which is introduced, in impregnated dirt, into wounds—sometimes very slight in [illegible] of the face, hands, and feet. I noted that the incubation period of tetanus (while the toxins generated by the bacillus are disseminating in the blood, and before the dreadful symptoms develop) is from five days to a fortnight, that prophylactic injections of antitetanus serum, if given immediately after the injury, will almost certainly ward off this disease, which before its introduction was fatal in more than [illegible] fifths of the cases; that practically all health departments are now open on Independence Day, prepared to provide this antitoxin, when asked for it by telephone; that in the event of any wound, immediate [illegible] heroic surgery is imperative, and that if any such wound be examined under the microscope for the suppuration, the latter's absence after several examinations should greatly allay fear of the disease developing.

During several years past humane citizens, anxious to prevent these deaths and sufferings among our young people, have striven to interest public opinion in the substitution of celebrations of the great national holiday every whit as patriotic, while at the same time much safer and saner, and at least as conducive to pleasure and patriotism as those that have hitherto obtained, and year by year the success of these endeavors has been progressive. I would here sketch what has been done in these premises during the past twelvemonth.

Last year Independence Day fell on Sunday—the chief reason, no doubt, why the number of tetanus deaths, which had theretofore been steadily decreasing, doubled in 1909 those of the preceding year. The coming holiday falls on Monday, so that the festivities are likely again to be spread over three days. There seems moreover to have been relaxed authority regarding the use of fireworks, especially in Illinois, Massachusetts, New Jersey, New York, and Pennsylvania; this relaxation regarding especially the use of blank cartridges resulted in an increase of tetanus cases. Nevertheless, last year there was gratifying evidence of an increased public sentiment in favor of more rational celebrations. Two cities, Washington and Cleveland, joined those which had already passed prohibitory ordinances, and Chicago enforced a restrictive ordinance, with the result that no casualties were reported from Washington, only four slight injuries for Cleveland, and less than half the usual number of accidents—with no deaths—for Chicago, although this latter city had 12 deaths in 1908 and 16 in 1907. Prohibitive ordinances have been more effective than restrictive ordinances, the latter in turn are much better than the do-nothing policy.

As I have intimated, year by year efforts have been progressively making to substitute sensible amusements and enthusiasms for the explosive celebrations that have resulted in 794 tetanus deaths among our children in seven years. Springfield, Mass., while abating not a jot—indeed, rather enhancing—a spirit of genuine patriotism, has provided parades, floats representing historic incidents, picnics; and, finest of all, an annual chorus drilled by skilled leaders in the mass singing of national airs and popular songs. How worthy of emulation by other communities! How gratifying to all but the "business interests" involved!

The Journal of the American Medical Association has for seven years past demonstrated by statistics the appalling number and character of the casualties resulting from our wonted celebrations. As I have noted, blank cartridges alone furnished 794 tetanus deaths in those years; and the disease of which these children and youths—all under eighteen—are the victims is the most agonizing known to medical science. The deliberate tortures of the Inquisition hardly paralleled such suffering. If, in the face of these undoubted facts, it will be decided to adhere to the old order of things, far more merciful would it be to pick out a hundred or more youths the coming Fourth and deliberately shoot them in any market place. [illegible] in the light of our [illegible] knowledge, now rests squarely upon our [illegible] to this regard [illegible], to [illegible] by our constituted [illegible] them firmly to this duty. [illegible]

All classes of publications are taking up the propaganda begun by the American Medical Association; newspapers and magazines are utilizing the statistics which its Journal has submitted. One magazine imagines the results of a vote by Congress to sacrifice each year one unknown boy as a national Fourth of-July offering—the newspaper extras announcing the grotesque and extraordinary action, editorial denunciations of our law-makers, the public agitation and supreme indignation, petitions to Congress and the President, the tumult that would inevitably attend the execution of such an act of madness. Yet we have supinely been allowing, year after year, with the absolute certainty of the result before us, the slaughter of hundreds and the mutilation of thousands of our children, with the natural consequence in suffering, torture of mind, and desolation in many households.

Our people are indeed well on the way to grasping the logic of these presentments. Everywhere individuals, civic societies, and kindred organizations are at work, measures are on for the formation of a national committee to promote a "safe and sane Fourth", municipal authorities are acting understandingly, to legislation hitherto enacted, more has been or will be added this year. The action of the Medical Society of the State of Pennsylvania is especially noteworthy by reason of its comprehensive character. Its Committee on Independence Day Fatalities recommends Legal control of the importation, manufacture, and sale of explosives used only for purposes of celebration; municipal control of the use of firearms and of fireworks during the Fourth-of-July season, municipal participation in substitution methods, the organization of societies for both control and substitution purposes, the most complete possible systematic use of tetanus antitoxin, and other medical measures in both the [illegible] of tetanus and sepsis (blood poisoning) [illegible] schools [illegible] of the [illegible] possib[illegible] matte[illegible] Indep[illegible] the [illegible]

In [illegible] manif[illegible] been [illegible] para[illegible] from [illegible] police [illegible] woul[illegible] on th[illegible] and [illegible] and [illegible] the [illegible] wor[illegible]

[illegible] the [illegible] mile course for the [illegible] was [illegible] with [illegible] Orville Wright [illegible] 1[illegible] circling twice [illegible] course and executing some graceful maneuvers [illegible] sharp turns and sudden dips. Walter Bro[illegible] of the five aviators Orville Wright trained [illegible] at Montgomery, Ala., is reported to have made four [illegible] course (6 miles) in [illegible] minutes or at the rate of [illegible] 3 3-5 miles an hour.

[illegible] Mr. [illegible] height [illegible] [illegible] 384 4-5 feet [illegible] taking the height, he attained an altitude of 1 900 feet in 7 minutes. It took him a half hour to reach the greatest height. He descended in circles the same as when he ascended, and when within a hundred feet of the ground, he shut off the motor and glided to earth. The following day Brookins continued his exhibition flights and gave another demonstration of his skill as an aviator by flying for nearly an hour in a stiff wind. After doing many fancy maneuvers he made a glide and landed almost at the starting point. One of the other Wright machines had trouble with its motor and was unable to make more than a half circuit of the course. There was very little flying this day on account of the wind.

The third day of the meet Brookins again attempted to make an altitude record, but only succeeded in reaching a height of a little over 1,700 feet. After the usual performance of the five Wright biplanes, Orville Wright made a flight in which he performed numerous and daring evolutions over the trees in the surrounding fields. His machine flew very steadily and made sharp turns, but did not show the speed that Hamilton exhibited in his Curtiss biplane at Mineola.

On the fourth day of the meet aviator Brookins well nigh outdid Orville Wright in the fancy maneuvers he executed and in the sharp turns he made. He created a new world's record for turning by making two turns in 6 2-5 and 6 1-5 seconds respectively. The circle he described was less than 150 feet in diameter. The best previous record of this character is said to have been made by one of the Wrights recently at Dayton. Brookins again attempted to break his altitude record, but only succeeded in reaching 3 800 feet after a 45-minute ascent. He required only 10 minutes to descend from this height. Two and three aeroplanes were frequently flying together during the afternoon, and at one time the motor in aviator Hoxsey's Wright machine suddenly stopped when he was at a height of 300 feet. He glided down in a straight line and landed in a field quite a distance away.

On the fifth day, Brookins again attempted, and this time successfully, to break his altitude record. After soaring in wide circles for 40 minutes, he reached a height of 4,503 feet. The machine was but a speck in the sky and on account of the haze and the lateness of the hour, it was sometimes momentarily lost to view. After apparently hovering for several minutes, he began a slow descent in wide circles. Brookins circled five miles to the east of the motor speedway and gradually closed in upon it. He had difficulty in seeing the track because of the gathering darkness. The motor stopped when he was only half way down and he was obliged to make a long glide. He finally landed in a farmer's yard a couple of miles from his starting point. The flight had lasted an hour and a half, and it was by all odds the best attempt at high flying that has yet been made.

The Indianapolis aviation meet did not draw the crowds anticipated. This was doubtless due to the fact that only one make of aeroplane was used. In order to have a good sporting event, various types of machines must compete. At the meeting in Montreal, from the 25th inst. to July 4th, there will be two Blériot monoplanes, in addition to the five Wright [illegible] and the biplane of J. A. D. McCurdy. There [illegible] be some other machines entered at the last [illegible]. Count Jacques de Lesseps, who recently [illegible] the English Channel, will pilot one of the [illegible] monoplanes. This machine has a 50-horse power [illegible] and will be able to outdistance the Wright biplanes, which have only 30-horse power engines. In all [illegible], there will be some interesting races at [illegible] international meet.

### [illegible] Information About Dishonest Patent Schemes.

[illegible] SCIENTIFIC AMERICAN has always made a prac[illegible] of exposing the snares and devices of the patent [illegible] promoter, as well as the fraudulent patent attorney. [illegible] the subject is by no means new to the readers of the SCIENTIFIC AMERICAN, it is one on which all [illegible] inventors should be thoroughly informed. The Editor of the SCIENTIFIC AMERICAN would like to receive from [illegible] readers of this journal, letters in which they narrate their personal experiences with dishonest promoters and attorneys. Such letters will be published in due course, and should not only be of interest in themselves, but should serve as a warning, thereby protecting others against such snares.

The staff of the Bureau of American Ethnology of the Smithsonian Institution has recently been increased by the addition of two ethnologists who have come to their work with the prestige of high university distinction. The first of these, Dr. Truman Michelson, studied comparative philology at Harvard, and then continued his studies abroad at the universities in Leipsic and Bonn. He then taught comparative philology at the University of Missouri in Columbia, and more recently has been a student under Boas at Columbia University in New York city. He has published various papers in his specialty, and has in press a revision of Jones's "Grammar of the Fox Language." Dr. Michelson will undertake to determine the linguistic interrelationship of the greater groups of the Algonquian languages. For this purpose he will visit during the summer the Blackfeet reservation and the Northern Cheyenne reservation in Montana, then the Windriver in Wyoming, and Menomoni reservation in Wisconsin, and the Micmac reservations in Quebec and New Brunswick. The other of these new appointees is Mr. Paul Radin, who has prosecuted advanced studies in anthropology at the universities in Berlin and Munich, and during the last four years has been a student under Boas and Farrand at Columbia University in New York city, from which institution he is soon to receive his doctorate. Mr. Radin has taught at the College of the City of New York, but has decided to relinquish teaching in order to follow ethnological studies as a life work, and to him the Bureau has assigned special investigations among the Winnebago Indians of Nebraska. Mr. Radin is the author of numerous papers which have appeared in the Zeitschrift für Ethnologie, the Journal of American Folk-lore, and the Proceedings of the Royal Anthropological Institute of Great Britain and Ireland.

# THE GERMAN DREADNOUGHT "NASSAU"

## THE FIRST OF THE GERMAN FLEET OF DREADNOUGHTS TO BE COMPLETED

In view of the great secrecy which has attended the construction of the "Nassau," the type ship of the fleet of German dreadnoughts some surprise was expressed upon the first public view of the ship, that she possessed, as a dreadnought, no features of marked novelty. To the people of the United States, there is something familiar about the arrangement of her main battery, with its armament of heavy guns carried in six turrets, one forward and one aft of the center line, and four arranged amidships quadrilaterally. Their thoughts will be carried back some twenty years to the time when the plans of our first battleships "Oregon," "Massachusetts," and "Indiana" were made public. The distinctive feature in these vessels was the heavy battery which they carried and the novel plan upon which it was disposed, the pairs of 13-inch guns being carried in turrets forward and aft and the pairs of 8-inch guns being mounted in four turrets two on either beam, arranged at the four corners of the superstructure. This, it will be observed is practically the plan followed in the ships of our own navy, the guns are all mounted upon the longitudinal axis of the ship, and consequently the whole power of the 12-inch battery can be brought to bear on the broadside throughout a wide arc of training.

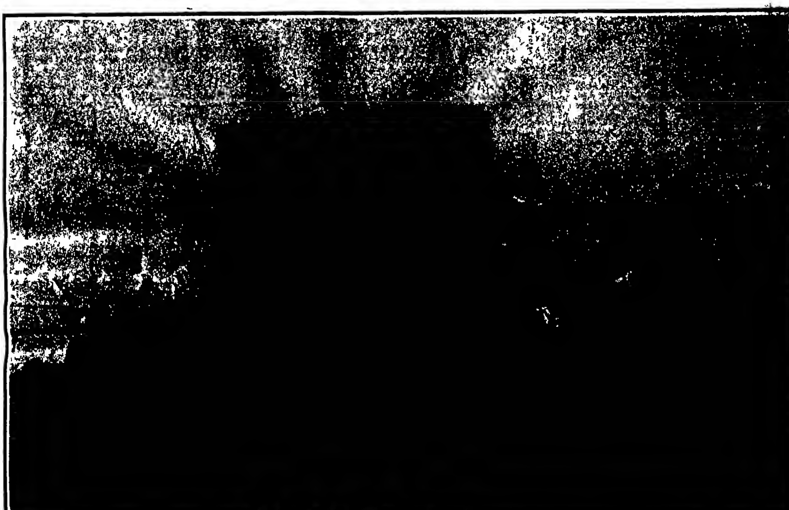
In justification of their adoption of the quadrilateral system of mounting, the Germans announce their conviction that in the engagements of the future there will be more fighting in the end-on or quartering position than the advocates of the all-centerline system of mounting believe, and they emphasize the fact that the "Nassau" can not only concentrate six heavy guns in the end-on position, but that she could deliver this heavy fire, should the exigencies of an engagement demand it, both forward and astern at the same time. Furthermore, there is a certain advantage in the fact that two guns and four turrets are held in reserve on the lee side and are greatly protected by the turrets which are in engagement on what might be called the weather fighting side of the ship.

Should the weather guns be disabled, it would be possible for the fleet to make a complete turn of 180 degrees, and bring four big guns, with their gun crews entirely fresh, into the fight.

To these arguments it will be answered that, by moving one of the four amidship turrets forward and placing it at a sufficient height to fire above the foremost turret, and removing another of the turrets aft and giving it a similar relation to the aftermost turret, not only would the broadside fire of the "Nassau" be increased from 8 to 12 heavy guns, but the end-on fire would be strengthened by the addition of two more guns, raising it from a concentration of six to one of eight guns. This is the method adopted in the new Argentine cruisers, the most powerful dreadnoughts now under construction, which will be able to fire eight guns ahead or eight astern, or twelve on either broadside.

However, in estimating the merits of warship design, we must be careful to bear in mind the question of displacement, which in the "Nassau" stands at the very moderate figure of 18,500 tons; and, if we remember that our latest dreadnoughts have run up to 26,000 tons, it must surely be admitted that the Germans, in view of the limited displacement of the "Nassau," have turned out a decidedly [illegible] ship.

The following dimensions, which have been obtained through the courtesy of the German Navy Department, may be taken as correct: Length, 453 feet, beam, 89 feet, draft, 26½ feet; displacement, 18,500 tons; normal coal supply, 950 tons. The "Nassau" is driven by triple engines, and on her trials considerably exceeded her contract speed of 19 knots and may be set down as a 20-knot vessel. The armament consists of twelve 11-inch, twelve 6-inch, and sixteen 3.4-inch guns. She is protected by eleven inches of Krupp armor on the belt and the barbettes and turrets, and twelve inches on the conning-tower.



Length, 453 feet. Beam, 89 feet. Draft, 26½ feet. Displacement, 18,500 tons. Normal coal supply, 950 tons. Armor: Belt, 11 inches; turret and barbettes, 11 inches. Armament: Twelve 11-inch, [illegible] guns; twelve [illegible] guns; sixteen [illegible] guns.

"NASSAU"—FIRST OF THE GERMAN DREADNOUGHTS.

Incidentally, it may be mentioned that the Japanese have adopted the same arrangement in the first dreadnoughts built for their navy.

Obviously, the principal disadvantage of the system is that the ship, although she mounts twelve heavy guns, can bring only eight of them to bear upon either broadside, at least four guns being masked by the superstructure or by the other turrets while she is fighting a broadside engagement with the enemy.

---

**An English Judicial Opinion of Complex Patents.**

The complexity of patent specification phraseology, and particularly the bewildering character of the claims of an American patent, were recently made the subject of a decision of the House of Lords. The case, which five members of the House were called upon to decide, was that of Linotype and Machinery Limited vs. Hopkins. We presume that the specification, which called forth the condemnation of the Lords, was simply the American specification filed in England without any change. The following is an extract from the decision, the unanimous judgment of the five members of the House of Lords.

"The appellant (i. e. the patentees) has filed a specification which resembles a treatise in its length; it contains no less than sixty claims; there is infinite redundancy and repetition and constant reference to illustrations which are not very easy to follow. Altogether it is a document which needs the most prolonged and penetrating study in order that anyone, who wishes to work out problems of invention in this class of industry, may know where they stand and how they may be free from the danger of infringing former patents.

"The point whether this patent is good or not does not arise in this case, but I think it is my duty to state explicitly that those who file and secure specifications must take the risk of having the whole thing declared void for ambiguity. I have had occasion to observe that there is a tendency to frame specifications and claims so as to puzzle a student, and to frighten men of business into taking out a license for fear that their interpretation may be held erroneous, and they be found guilty of infringement. That is an abuse of the law and will be checked if occasion should require, by the simple process of declaring the patent invalid."

---

Uranium is found commercially in only two minerals in the United States, pitchblende and carnotite. Pitchblende, which is widely known because of its use as an ore of radium, occurs in commercial [illegible] in the United States only in Gilpin County, Colorado, where there are four mines that produce it. Carnotite occurs as a yellow powder in [illegible] in Utah and Colorado.

# Hamilton's Round-Trip Aeroplane Flight from New York to Philadelphia

## A REMARKABLE CROSS-COUNTRY FLIGHT

Only a few days after Glenn H. Curtiss's flight from Albany to New York, aviator Charles K. Hamilton made a more daring and thrilling flight from New York to Philadelphia. This second flight was planned by the New York Times and the Philadelphia Public Ledger, and aviator Hamilton, carrying a letter from Mayor Gaynor of New York to Governor Stuart of Pennsylvania, executed the flight on schedule time During a considerable part of the trip he raced a special train which at times found difficulty in keeping up with him.

The start was made from Governor's Island at 7 36 A M on Monday, June 13th The actual start took place only after Hamilton had broken a propeller in attempting to start the first time, due to the blade striking a stick that lay upon the ground As soon as he had substituted a new propeller—the very one used

# New Filtered Water Supply for the City of Pitts[illegible]

## HOW THE ALLEGHENY RIVER WATER IS PURIFIED AND DELIVERED INTO THE CITY MAINS

There has recently been completed for the city of Greater Pittsburg an ambitious scheme of pure water supply which represents the very latest developments in work of this character. The site for the filtration plant is on the north bank of the Allegheny River about seven miles above the point where it joins the Monongahela to form the Ohio. The new plant is located a short distance above and on the opposite side of the river to the Brilliant Pumping Station which formerly took water from the river direct. The plant extends along the river front for 3,700 feet and covers some 225 acres.

At the upstream corner of the site low-lift pumps located in what is known as the Ross Point Pumping Station raise the raw water to a central receiving or sedimentation basin of 20,000,000 gallons capacity. On each side of this receiving basin is a larger sedimentation basin and the three have a combined capacity of 130,000,000 gallons. From the central receiving basin water flows to the rest of the plant by gravity flowing first to the sedimentation basin and thence to the slow sand filters from which it is conveyed to a covered filtered-water reservoir on the bank of the river. From the reservoir the water passes through two steel conduits laid under the river to the high service Brilliant Pumping Station which lifts the water to the storage reservoirs that supply the distribution system of the city.

The intake has been built back of a revetment which has been constructed along the river bank in front of the Ross station and it consists of a concrete chamber to which the river water is admitted by sixteen four-foot conduits arranged in two horizontal rows of eight each. From the intake the water passes through a 124-inch conduit for a distance of 330 feet to the pumping station.

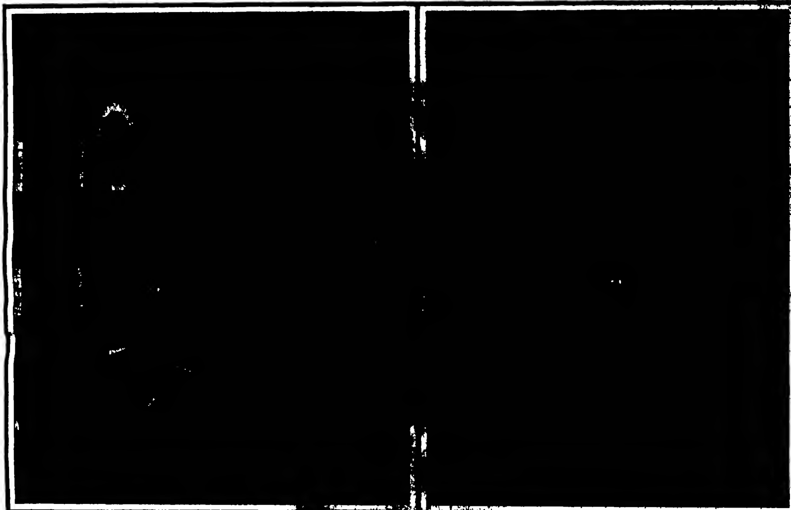
The Ross Point Station measures 128 by 200 feet in plan. The steam generating equipment consists of eight 350-horse-power horizontal Sterling water-tube boilers arranged in batteries of two each. Extending along the front of the building is a pump pit 88 feet wide and 16 feet deep. In this are placed four Allis-Chalmers horizontal shaft single-stage double-suction centrifugal pumps, each direct connected to an Allis-Chalmers vertical cross-compound condensing Corliss engine. Each pump has a rated capacity of 35,000,000 gallons per 24 hours when pumping against a total head of 46 feet of which not more than 14 feet is suction lift. The impellers of the pumps are 11 feet 3 inches in diameter. The suction nozzles are each 28 inches and the discharge nozzle is 36 inches in diameter. The external construction of these pumps is clearly shown in the accompanying illustration.

The 100-inch conduit before mentioned as conveying the raw water extends under the pump pit and forms a suction pit for the pumps which discharge through branch connections to a 96-inch rising main that extends 1,853 feet to the central gate-house. The rising main is built of half-inch riveted steel plates surrounded by concrete. The flow of water through the rising main is measured by a 96-inch Venturi meter with a 50-inch throat—the largest meter of this type ever built. At the discharge end of this main is a central gate chamber 50 feet by 53½ feet which controls the flow of water to and from the sedimentation basin. Above this chamber is built the administration building from which the entire operation of the plant is controlled and directed.

There are three sedimentation basins, the two larger ones covering about twelve acres and the smallest about three acres. Water is carried to a depth of about fifteen feet and the total capacity is 130,000,000 gallons or about one day's supply. The 56 filters have each a surface of one acre and a capacity of 3,000,000 gallons per 24 hours. Each filter bed measures 163 by 263 feet, and it is completely roofed over. The floor is of concrete and the groined-arch roof is supported by 170 columns each 22 inches square spaced 16 feet center to center. The under drainage or collecting system consists of a central main collector extending down the central bay, with lateral collectors of vitrified tiles in each side bay laid in open joints. The collectors are covered with one foot of gravel varying from one-fourth inch to three inches in size, above which is a layer of sand four feet thick. An interesting feature is the new system for scraping the beds and cleaning and replacing the sand. The work is done by machinery instead of by hand, and the system is the most complete in this country.

The collectors beneath the filter beds lead to conduits in the galleries, and these connect with the main conduit, which leads to the filtered-water reservoir, which has a capacity of 50,000,000 [illegible]. The latter is built of plain concrete with [illegible] roof, the latter being carried on 775 round [illegible] inches in diameter, 21½ feet high, spaced 12 [illegible] ter to center. These arches are believed [illegible] largest of this type that have ever been b[illegible]

From the filtered-water reservoir the w[illegible] ried by two 72-inch steel pipes beneath [illegible] the Brilliant Pumping Station. Originally, [illegible] ing station had a daily capacity of [illegible] gallons, the plant consisting of two 10,00[illegible] Holly engines and two 15,000,000, and fou[illegible] gallon Allis-Chalmers vertical cross-comp[illegible] ing engines. At the time of the build[illegible] filtration plant two additional 15,000,000-ga[illegible] Allis-Chalmers pumping engines were [illegible] grounds of the filtration plant, which [illegible] acres have been developed into a very [illegible] The filters and filtration reservoirs which, as we [illegible] noted above are covered, have been overlaid [illegible] eral feet of soil which has been sodded. Macadam road drives planted with trees have been laid out and a natural wooded slope at the back of the plant has been left unchanged. The delivery of filtered water was begun early in 1908. The full capacity of the original filters was reached in 1909, and with the construction of the last ten filters, the entire city of Greater Pittsburg will be supplied with pure drinking water. For our illustration and the particulars upon which the above article is written, we are indebted to the courtesy of the Allis-Chalmers Company and Industrial Progress.



One of the four huge centrifugal pumps each of which can lift 35,000,000 gallons per day against a head of 46 feet. The two suction nozzles are 28 inches and the one discharge nozzle 36 inches in diameter. The impellers are 11 feet 3 inches in diameter.

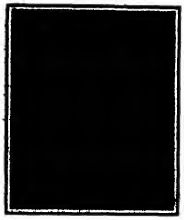
# The Home Laboratory

[The Editor of the Home Laboratory will be glad to receive any suggestions for this department and will pay for them, promptly if available.]

## WANDERING CHEMICALS

BY PROF GUSTAVE MICHAUD COSTA RICA STATE COLLEGE

To cause two objects to change place that is, to pass from one vessel into another and *vice versa* is a trick sometimes done by conjurers What is new



CONTENTS OF TUBES BEFORE SHAKING

in the performance described here is the evident non-intervention of the magician and the possibility of watching the trick closely in full light The vessels used are two perfectly transparent glass test tubes Every spectator can see that they contain nothing but the two substances about to change place One of these is a fluid, transparent, colorless liquid which fills about one-half of the tube The other tube contains nothing but a white, opaque powder Both tubes are given to some skeptical spectator, with the request that they be kept well apart, one tube in each hand, and that the experimenter should remember which the liquid or solid is kept in the right or left hand The skeptical person is then ordered to close the tubes with his thumbs and to shake them After having complied with this request he will find that the two substances have apparently changed places, the tube which contained a white opaque solid now contains a colorless transparent liquid and the tube which contained a watery liquid is now filled with a white opaque perfectly solid substance

Some curious and but little known properties of organic substances are used for this performance. One of them is the property of salol to remain in the fusion state with such a tenacity (in open vessels in presence of unfiltered air) and for such a time that no other substance equals it in that respect, except perhaps the metal gallium Salol is used in medicine for some kinds of intestinal troubles and is sold at every druggist's Some ten grammes of it are placed into a clean and dry test tube care being taken not to leave crystals adhering on the walls of the tube

CONTENTS OF TUBES AFTER SHAKING.

The chemical is then melted over any flame (A candle will do, as the fusion point of salol is but 43 deg Centigrade.) Once liquid, it is heated a trifle over its fusion point, so as to melt any particles of salol left [illegible] This is then allowed to cool and is ready for the experiment, even two or three hours after being made. [illegible] to and fro will not cause [illegible]

the crystallization but vigorous shaking for about ten seconds invariably transforms the liquid into a solid white mass At the moment of the solidification the cold tube instantaneously becomes hot

The property of solid camphor to rapidly melt into a liquid compound whenever ground or shaken with solid chloral hydrate is used in the other test tube The two chemicals must be finely powdered and the camphor is sprinkled with a few drops of alcohol before being ground The two white powders look alike and are superposed in the tube two parts in volume of camphor being taken for one of chloral hydrate The shaking rapidly mixes and liquefies them

Large tubes or bottles of any thickness can be used when the experiment is made in a hall. The fusion of salol is then produced in a water bath

## GEISSLER TUBES FROM ELECTRIC LIGHT BULBS.

BY JAMES BAILEY

Many people have wished to perform experiments with Geissler tubes but owing to their high cost have not been able to do so

By the following simple and inexpensive method anyone who possesses a one inch or larger induction coil can make a very good substitute for a Geissler tube from any of the standard electric light bulbs Burned out lamps or lamps in which the filaments are broken give the best results and can be had for next to nothing The effect is much better if the filament is broken into fine pieces, as it then does not interfere with the discharge in the bulb Metal filaments can easily be broken by striking the lamp with the hand but in carbon lamps the filament is sometimes so tough [illegible] amount has leaked in [illegible] real Geissler tubes

Allowing just the right amount of air to leak in is a rather difficult process but it can be done most simply as follows

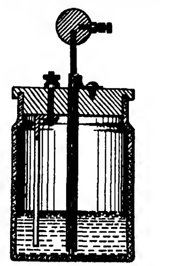
Instead of making a wax cone as in Fig I make a bell shaped piece as in Fig III With a sharp file nick the bulb where the end of the wire will come The purpose of this nick is to help the spark puncture the glass It should not be made deep enough to allow any air to enter the bulb Next stick the wax bell on the bulb so that the end of the wire rests in the nick Connect to the coil as before and turn on the current The spark will jump through the glass and whatever air is in the bell will leak into the bulb By varying the size of the bell different colored glows may be obtained The wax bell in Fig III shows about the size for the best results with 16-candle power lamps Different lamps give different results so that the exact size of the bell cannot be determined and striations are more or less a matter of luck Almost every bulb made as above will show beautiful color effects each different from the other and the results are well worth the trouble

## CONSTRUCTION OF A SIMPLE ELECTROLYTIC INTERRUPTER.

BY GEORGE F WORTS

The electrolytic current interrupter described here may be used in place of the troublesome vibrator on spark coils. It is to be operated on 50 to 220 volts [illegible] direct or alternating current The interruptions obtained with this type of interrupter are very high, being in the neighborhood of 1 000 per second

The electrolyte and electrodes are contained in a wet battery jar A wood plug should be turned to fit tightly in the top of the jar and boiled thoroughly in paraffin to protect it from the acid fumes A glass tube 6 inches long with an internal diameter of ¼ inch should be procured and a hole slightly larger than the external diameter of the tube bored through the center of the wood cover The tube is held in position by a heavy brass spring pressing against it For the anode a ⅛ inch round brass rod should be straight-



A SIMPLE ELECTROLYTIC INTERRUPTER

ened so as to slide very easily through the glass tube One end of the rod should be squared off and the other end threaded and a tapped brass ball fitted to it This weight by gravitation feeds the rod into the solution as it is used One side of the ball should be tapped and fitted with a binding post for connecting purposes The cathode consists of a lead strip 1 by 1 by ⅛ inch suspended in the solution from a machine screw the threaded end of which terminates in a binding post for connections To assemble Fill the jar a third full with a 10 per cent solution of sulphuric or nitric acid place the wood cover on firmly lower the glass tube through the hole till it is ¼ inch from the bottom of the jar and tighten the spring against it Then put the rod through the glass tube till it is resting on the bottom of the jar In use when the circuit through the apparatus is closed non-conducting bubbles form and break on the anode thus interrupting the current If the interrupter is used on alternating current the anode will wear down quickly Connections using alternating current are identically the same as direct but without regard to polarity as alternating current constantly reverses poles If intended for continuous work the electrolyte should be cooled by running water through a coiled glass tube in the bottom of the jar This interrupter will successfully operate coils from the small sizes up to the 10 inch size and is especially desirable in wireless telegraphic transmission as it aids materially in the production of a penetrating high frequency wave

## DEVICE FOR TESTING ELECTRIC WIRING

BY H WARD E NICHOLS

In testing electric wiring for open circuits grounds or short circuits it is often necessary to skin the insulation from the wires under test in a number of places so as to connect them to a magneto or other testing device The accompanying illustration shows

TESTING NEEDLE FOR INSULATED WIRE

a device which does away with this necessity for it contains a sharp needle point which can be easily pushed through the insulation until it makes a good electrical contact with the wire within The device is made out of a hard wood handle bored throughout its whole length to the diameter of flexible lamp cord The small end is then counterbored to a larger diameter and a plug is made that will drive tightly into the counterbore The next step is to procure a large sized sewing needle which is driven through the plug as shown in the sketch The eye end of the needle is soldered to a length of lamp cord which is passed

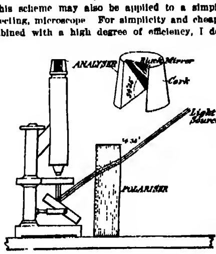
through the handle as shown The plug is then driven into place and the testing handle is ready for use

### POLARISCOPE ATTACHMENT FOR MICROSCOPES.

Illustrated herewith is a bit of apparatus by means of which polarized light may be used with any microscope without changing the instrument itself The polarizer consists of one dozen 4 x 5 inch glass negatives which have been thoroughly cleaned and dusted, and are contained in the original box, which has its top and bottom cut out, leaving just enough card around the edges to hold the plates in position

The analyzer comprises a piece of blackened cork with a wedge-shaped slot cut in one side and a bit of black mirror firmly pressed into position in the slot at the polarizing angle This rests on the eyepiece of the microscope and may be turned at any angle in the horizontal plane The black mirror is made of plate glass or cover glass, coated on the back with a mixture of lampblack and shellac varnish or, if more convenient, lampblack and glue The drawing shows the arrangement of the apparatus with the Nicols' crossed A small scale may be attached to the top of the analyzer, so that the angle through which it is turned may be noted

This scheme may also be applied to a simple, or dissecting, microscope For simplicity and cheapness, combined with a high degree of efficiency, I do not think this apparatus can be excelled The pleasure to be derived from its use is infinite



MICROSCOPE ARRANGED AS POLARISCOPE.

### AN ELECTROPLATING OUTFIT
#### WITH PRACTICAL WORKING FORMULÆ

BY A. J. JARMAN

Those who wish to undertake the electro-deposition of metals upon a small scale whether as a business or for pleasure will find that the apparatus and utensils here described will meet the ordinary requirements

The photograph reproduced herewith shows the wooden depositing tank and battery of an outfit in actual use The battery cells are made exactly as explained on page 445 of the SCIENTIFIC AMERICAN of May 28th 1910

The depositing tank is made in the same way, with the exception that the joints are put together with a very thick India rubber cement of the kind used for repairing tires The woodwork at the joints is first coated with the cement, both at the grooves and the ends, and is allowed to stand for an hour or two, when it is coated again and put together either with nails driven in diagonally or with screws The excess of rubber must be wiped off In the course of about twenty four hours the inside of the tank must be coated with a burning hot solution of paraffin Unless the paraffin is very hot, it will not penetrate the pores of the wood sufficiently to make it impervious to any of the chemical solutions that the tank may contain The wood used in making a depositing tank must be well seasoned If possible use old boards one inch thick so that when planed the board is not less than seven-eighths of an inch thick, and at all times place cleats across the bottom, so that it will stand clear of the floor or work bench The rubber cement used for the joints will not be affected by any of the depositing solutions The tank illustrated measures 5½ inches wide, 12¼ inches long, and 11 inches deep Five such tanks as these should be made, to contain the following cold working solutions, for silver, nickel, brass copper and zinc Gold and alkaline coppering solutions must be worked hot, as will presently be described

*Silver Plating* - Dissolve 2½ ounces silver in a glass flask by adding 3 ounces nitric acid and 1 ounce distilled water Heat the flask slightly and place it where the red nitrous fumes will pass off into a flue, or out of doors. When the silver has become dissolved, add a quart of distilled water, stir the mixture well, then add gradually about 5 fluid ounces pure hydrochloric acid, stirring the mixture well with a glass rod. Place the flask in a dark place while the white precipitate (chloride of silver) is settling. Pour off the clear liquid, add another quart of water; stir well, allow it to settle, decant; and wash a third time. This will free the precipitate of impurities formed. Dissolve ½ pound cyanide of potassium in ½ gallon of distilled water When completely dissolved, add a small quantity at a time to the chloride of silver Stir this well, and continue to add the cyanide solution until the chloride of silver has only just been dissolved. Allow a little time to elapse between each addition. When all the chloride of silver is dissolved make up the quantity to 2½ gallons with distilled water This will be the right quantity to fill the wooden tank, with one ounce of silver to the gallon Let this solution stand for twenty four hours, so that all dirt will settle, and then pour the clean solution into the tank. The solution is now ready for use.

Two sheets of fine silver about 5 inches square must be used for the anodes, suspended by either copper or silver wire hooks upon the copper rod (shown in the illustration) attached to the wire from the carbon of the battery, while from the bent copper rod the articles to be plated must be suspended, this rod being attached to the zincs of the battery The articles to be plated must be cleaned by boiling them in a strong solution of common washing soda for twenty minutes, rinsing in water, and scouring them individually with a stiff nail brush dipped in pumice powder or brick dust. Articles of German silver, brass, or copper, after scouring and being attached to the slinging wire, must be dipped into a solution of one ounce of nitrate of mercury in a gallon of water This will give a chemically clean surface and cause the silver to adhere firmly when the deposit takes place in the silver bath. Three or four spoons or forks should be submerged in the plating liquid quickly, before the [illegible] of silver is [illegible] the conducting [illegible] with an [illegible] as it [illegible] both anodes [illegible] 15 [illegible] articles [illegible]

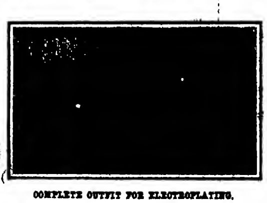
[illegible]

Only [illegible] cally clea[illegible] place it [illegible] at once, [illegible] color of [illegible]

*Copper Plating*—Articles [illegible] being nickel plated must be coated with a deposit of copper in the alkaline coppering bath, which can be used either cold or hot. If used hot, an enameled iron boiler will answer the purpose, but the heat must not exceed 130 degrees Fahrenheit for a bath of the formula given Dissolve ¼ pound sulphate of copper in ½ gallon hot water Also ½ pound carbonate of potash in 1 quart of water, and about 10 ounces cyanide of potassium in 1 quart water Add the carbonate of potash solution to the sulphate of copper Stir the mixture well Add enough strong liquid ammonia to dissolve the precipitate Then add gradually the cyanide solution until the blue color disappears. Make up to 2 gallons with distilled water, and after allowing the sediment to subside, pour off the clear liquid into the depositing tank. Have two anodes six inches square using the second anode according to the number of articles to be plated The two battery cells above referred to will perform all the work of deposition that this article describes. The cleaning of small iron or steel articles should be done just as described above for silvering. When the articles are coppered they must be scratch-brushed before receiving a deposit of nickel, silver, or gold; then scoured with fine pumice and water. They will then take a fine deposit of these metals.

*Gold Plating*—Electro-gilding in a small way is best done by making the gold solution as follows Dissolve in 1 quart of hot distilled water 1 ounce of cyanide of potassium. Take a small porous pot and fill it about two-thirds full Place it in the inner vessel of an oatmeal kettle, and pour in this vessel the balance of cyanide solution. Pour a quart of hot water into the outer vessel, and bring it to the boiling point. Take a strip of sheet copper, fix a piece of copper wire to it, and insert this into the porous pot. Attach the wire to the terminal of the zinc of the battery, and a piece of sheet gold to the wire coming from the carbon of the second cell of the battery. Note the weight of the gold. Place the sheet gold in the liquid that surrounds the porous pot, and allow the action of the two cells to continue until 1½ pennyweight has been dissolved from the sheet gold. Remove the porous pot; throw away its contents, use the remaining liquid for the gold depositing, and the piece of sheet gold can be used for the anode. Any article after being well cleaned can be coated with gold in this bath, giving a very rich color. Stale beer is the best liquid to use with a scratch brush in brightening the deposit previous to burnishing. The brass wire brush used should be finer for gold than for silver The articles after rinsing should be dried in hot boxwood sawdust.

*Zinc Plating*—Articles can readily be coated with zinc by using the following solutions (Watts's process) 2½ gallons water, 1 pound cyanide of potassium, 10 ounces of 0.880 ammonia. Place this in one of the tanks. Fill two large porous pots with a plain cyanide solution, consisting of 4 ounces of potassium cyanide to 1 quart water. Place a strip of sheet copper the width of the porous pot in each, and connect the copper with the battery as for gold, using two large clean zinc plates in the ammonia cyanide solution until about 6 ounces of zinc have been dissolved. Remove the porous cells and throw the contents away.



COMPLETE OUTFIT FOR ELECTROPLATING.

Add 5 ounces carbonate of potash, stir until dissolved, let the liquid stand until the dirty matter has subsided, and then siphon off the clear liquid, which is now ready for use. Clean the articles as for silver, using sheet zinc for the anode A very fine deposit can be obtained by this solution The articles should be removed occasionally to see that the deposit is going on satisfactorily If not, scour them slightly with pumice and water, rinse, and return to the bath. When the deposit is complete, the articles may be left dead in color or scratch brushed.

*Brass Plating*—Electro-brassing can be done by the following solution, bearing in mind that metals of the same kind only must be attempted. Wrought iron, cast iron, or steel must be plated separately Make up the following solution 4 ounces cyanide of potassium dissolved in half a gallon of warm water, 1½ pounds carbonate of potash dissolved in ½ gallon water, 2½ ounces acetate of copper dissolved in 1 quart water, 5 ounces sulphate of zinc dissolved in ½ gallon hot water Let all the solutions be cold before mixing Add to the acetate of copper solution ½ pint strong water ammonia, 0.880 Just before final mixing, stir this well and add to it the zinc solution, together with another ½ pint strong ammonia. Stir this mixture well, then add the potash solution, and lastly the cyanide solution. Allow this to stand after making the quantity up to four gallons. At the end of about 12 hours pour the clear liquid into the depositing tank, for use. Clean the articles as for silver plating, use the battery coupled in multiple, and a large brass anode, arranged so as to regulate the quantity of surface in the liquid. The exact color can be obtained by raising and lowering the anode. After a quarter of an hour the articles must be removed, rinsed, scratch-brushed, and returned to the bath for the final deposit. In every case in the electro depositing of metals, especially in the gold and brassing, the color can be varied by moving the article to and fro in the solution during deposition. Silver is also affected by this means, the deposit being much whiter when the article is moved.

Pewter, lead, or zinc articles must be electro-coppered previous to silvering or gilding, as well as wrought iron and steel. Special solutions must be made for plating these articles upon a large scale without coppering.

---

A liquid japan for leather is made as follows: Take four pounds of molasses, half a pound of lampblack, half a pound of sweet oil, and an equal quantity of gum arabic, also half a pint of isinglass. Mix well in 14 pounds of water; apply heat, and when cool add one pint of alcohol.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

GARMENT-FORM.—R. T. PALKENBURG, New York, N. Y. This form is such as is used in stores, show windows, dressmakers' establishments and the like. The aim of the invention is to provide improvements in garment forms, whereby the body of the form can be readily adjusted to assume a desired pose and thus display the garment to the fullest advantage.

HAIR-COMB.—J. H. AHRE, East Orange, N. J. The invention relates especially to combs of the type used for dressing the hair, the particular improvement being to provide the comb teeth with channels for the purpose of receiving the dandruff dust, and various other impurities gleaned from the head by the action of the comb.

### Of Interest to Farmers.

MEASURE.—R C HARBRIDGE, Margo, Saskatchewan, Canada. The invention is an improvement in dry or liquid measures, which are constructed of one or more sections adjustably received one within the other, whereby the capacity of the measure may be varied. As many farmers do not possess scales, the measure is particularly adapted to their use.

### Of General Interest.

REIN-HOLDER.—K THARALDSON, Bloomingdale, Cal. This holder is for convenient attachment to the hip pad of the harness, and is arranged to hold the reins in position along the back of the animal, to allow free lengthwise movement of the reins, to provide sidewise movement thereof and to permit placing the reins conveniently and quickly in position in the holder or removing the reins therefrom.

KILN.—W DRAYTON, Kachelmacher, Ohio. In this patent the invention has reference to certain improvements in kilns adapted for burning brick or other ceramics, and involves a system whereby a plurality of separate portable kilns are arranged in series to form a continuously moving tunnel in which the bricks are first dried, then burned, and finally cooled.

GUIDE-RACK FOR FIRE-HOSE.—S. B WILLIS, New York, N Y. This inventor provides for directing from the ground the stream from a fire hose, a supporting structure upon buildings to guide the nozzle end of a hose pipe when shifted along a building, a permanent hose supporting carriage and operating track therefor disposed in line with the tiers of windows and for shifting the same from window to window, the means provided being operable from the ground.

PIPE.—W H STROSS, New York, N Y. The purpose here is to provide a simple pipe for smoking tobacco, which renders the use of tobacco more healthful, in which the tobacco smoke is cooled before entering the mouthpiece, so that it is rendered more palatable, and in which impurities are removed from the smoke.

MEDICINAL PREPARATION.—C HEININGER, New York, N Y. The object of this improvement is the provision of a simple and inexpensive lotion for use in various diseases of the eye, which has a pleasant and stimulating action with regard to the tissues, and which is particularly useful for the treatment of trachoma and like diseases.

AIR-COMPRESSOR.—D R ALLARD, Arleta, Ore. The main object in the present invention is the provision of means by which the force of the waves of the sea or other body of water may be used to best advantage for compressing air. The same action will take place from the rise and fall of the tide as well as from the force of waves and hence the invention contemplates a tide power device as well as a wave power device.

SAFE.—R. S. ELLIOTT, Laona, and G COOK, Gillett, Wis. In this case the invention is an improvement in safes, and the purpose is the provision of a safe especially adapted to resist the insertion of explosives thereinto, and to prevent the insertion of a sufficient amount to cause any damage by exploding the said explosive in detail and in small amounts.

TOY BALE.—A. HIRSCHWITZ and H MAUDRAIN, New Orleans, La. This bale can be made in any miniature size and will present the appearance of a cotton bale and thus be desirable in certain sections, especially the cotton growing sections, and will afford in connection with a simple hollow body portion, corrugated to heighten the resemblance to a cotton bale or other complete bale, means for receiving a drawer which can be utilized as a receptacle for confectionery or other suitable merchandise.

PROCESS FOR CONVERTING GLUE.—C. M. STRICKMAN, Cincinnati, Ohio. This invention refers to a process for converting or melting glue, and its object is to melt the glue in a very short period of time, thus avoiding the long continued application of dry heat at high temperature, which destroys the fibrous matter of the glue and diminishes its strength.

### Hardware and Tools.

NUT-LOCK.—J. C. AUSTIN, New York, N Y. In this instance the invention has reference to nut-locks for use with ordinary or special bolt nuts and the like, and it relates more particularly to a device of this class having a resiliently expansible body and provided with a threaded bore of varying diameter.

LOCK.—M. H. FARMER, Virden, Ill. One object of the invention is to provide a simple form of locking mechanism which may act in the manner of an ordinary spring lock until the door or other swinging member to which it is applied is shut, when the lock will immediately become "dead" and will require a key to unlock it.

COMBINED MATCH BOX HOLDER AND CIGAR-CUTTER.—E. OLDENBAUSCH, New York, N Y. The holder is adapted for receiving and protecting the common form of match-box, and it is the location, construction and arrangement of the cutter which embodies the main features of the invention. The cutter is secured to the end of the holder and operates to limit the inward movement of the box and to permit the box to be automatically opened upon insertion of a cigar within the cutter. The last does not interfere with the free opening of the box, and the top of the cigar removed by the cutter falls outside rather than inside the box.

### Heating and Lighting.

THERMOSTAT.—W ENTERLINE, Big Run, Pa. In the present patent the invention has reference to thermostats, and it has for its object the provision of one for use in regulating the flow of gas used to heat water in boilers, which is certain in its operation and one which may be manufactured and repaired at little expense.

HEADLIGHT BURNER.—C E POWERS, Baltimore, Md. The invention relates to headlight burners of the kind adapted to consume oil, the more particular purpose being to provide intermediate the lamp wick and the oil reservoir a member of peculiar shape and offering especial advantages relative to the flow of the oil from the reservoir to the wick.

INVERTED GAS BURNER.—E. STEIL, No 14 an der Apostelkirche, Berlin, Germany. The object is to so construct the burner that by the removal of the mixing tube of the Bunsen burner, which is detachable in the usual manner the gas nozzle is simultaneously moved into such a position that it is readily accessible, which presents the advantage that the clearing of the discharge aperture, which is frequently necessary, can be effected speedily conveni[illegible] of widening [illegible]

MOP WR[illegible] Minn. The [illegible] provide de[illegible] adapt the [illegible] edge portion [illegible] liable support [illegible] adjacent to [illegible] the side of [illegible] enable the [illegible] fibrous mop [illegible] from the m[illegible]

DISINF[illegible] MELVILLE, [illegible] vides a secti[illegible] ing tank to [illegible] to the disi[illegible] other, to dire[illegible] ing from the [illegible] last having [illegible] lower opening [illegible] in the bottom [illegible] communicating [illegible] ing on the latt[illegible] ported on arms [illegible] close proximity [illegible] ing chamber

### Machines and Mechanical Devices.

FLUID EXPANSION PRESS.—L. C TURLEY, Portsmouth, Ohio. The objects here are, 1 To shift the die cap into and out of position relatively to the die, by turning an expansive medium on and off for actuating the moving elements so that a single application is sufficient to cover the die and to squeeze within the same the article to be pressed, and that the release of the medium from the press not only restores the die to normal condition, but also removes its cap. 2 To enable the release of the medium to remove the cap by a plurality of motions, first raising the cap clear of the die and then shifting the cap in a lateral direction, the cap performing these movements universely whenever the medium is turned on.

SEPARATOR.—M L. JONES, Baltimore, Md. In this case the invention has reference to separators for centrally separating materials having a different specific gravity, and partake of rotatable means for separating a material having a lighter specific gravity from a material having a heavier specific gravity, and vice versa.

AUTOMATIC GUN.—G COLLBONI, New York, N. Y. The main objects here are to provide for maintaining the barrel at a comparatively low temperature, for regulating the quantity and pressure of the gas delivered to the piston; for more effectively transferring cartridges from the feed strip to the breech piece; for bracing the breech block against return movement at the instant of explosion, and for operating the firing pins.

TYPE-WRITER ATTACHMENT.—J L. MURPHY, Covington, Va. The object here is to provide an attachment which may be easily attached to and detached from a typewriter carriage, and which will support a plurality of superposed strips of paper, and pass them through the typewriter, and which will automatically separate the fair copy from the carbon and deliver it from the front of the machine, and will roll up the copy and retain it in such condition until removed.

CLUTCH MECHANISM.—F E SUDDOTH and W T S. WEAVER, Omaha, Neb. The object of the improvement is to provide a mechanism especially adapted for automobiles, but equally advantageous for other machinery requiring a variable speed, whereby the relation of the speed of the driven means to the driving means may be varied within the widest possible limits.

### Railways and Their Accessories.

METALLIC RAILROAD-TIE.—A S WASSON, Batavia, N Y. The improvement provides a tie having details of construction that prevent it from creeping endwise, or sinking into the roadbed, a further object is to provide effective means for securing track rails upon the improved cross-ties that may be readily released for track repairs and quickly resecured as occasion may require.

SAFETY GATE FOR RAILWAY CARS.—F T FILLION, North Platte, Neb. The gate is so constructed that it is held suspended or folded vertically out of the way, when cars are coupled, but is automatically released, and falls into position across the end of the car platform when the train is broken, that is to say, when the car to which the gate is attached is parted or uncoupled from the next one.

### Pertaining to Recreation.

TENNIS-COURT MARKER.—E A ROBINSON, Emporia, Kan. This improvement is in devices for marking the lines of tennis courts and other purposes and the object is to produce an implement which may be used for marking off on the ground the necessary lines, boundaries, etc of tennis and other courts and one which can be readily filled with the marking material and which can be used on uneven surfaces.

### Pertaining to Vehicles.

VEHICLE TOP.—H C MARTELL, Flint, Mich. This improvement is in a vehicle top and when the top is extended it forms an [illegible] the vehicle, and without [illegible] into and to de[illegible] front bow is [illegible] folded, it is [illegible] of space

[illegible] patents will [illegible] cents each [illegible] patentee title of [illegible] paper

### [illegible]ueries.

[illegible] when writing [illegible], subscriptions, [illegible] and address on every [illegible] printed at the head [illegible] 18th, 1910, or will [illegible]

[illegible] That introduc[illegible] reduces the num[illegible] of course plain ar[illegible] amperes being equal [illegible] divided by the resist[illegible] also always been under[illegible] resistance introduced into a circuit reduced also the effective voltage of the circuit after the current had passed through the said resistance and that the voltage would fall according as more or less resistance was introduced. The following experiment is therefore hard to explain if this is so. We connected two 110 volt lamps in series on a 220-volt circuit and in the opened point as shown below after the current had first passed through the lamps inserted a large standard voltmeter which read 218 to 220 volts. This was repeated many times with the greatest precautions as to connections and also on other sources of supply and the results were the same in a general way apparently no drop of any appreciable extent having occurred by the passage of the current through the lamps although of course the amperes were cut down. What is the explanation of this? Much discussion has arisen over it, and the claim made that the voltage should have been reduced.

A. The case of the lamps and the voltmeter as you describe it is no exception to Ohm's law. The resistance was not that of two lamps in series, but of two lamps and a voltmeter which had a resistance of many thousand ohms. The current in amperes became inconsiderable because the resistance was so high, and the voltmeter registered only the voltage. The voltage would be the same as if the lamps had not been in series in the line. No amperes were flowing, or at most a very small fraction of one ampere. The point is this: the voltage at the end of an open circuit is the same as that any where along the circuit. The *drop between any two points of a closed circuit* is proportional to the resistance between those two points. If the circuit which you show in your figure had been closed the lamps would have lighted, showing that current was flowing, and the voltmeter would then have shown 110 volts drop between the two terminals of each lamp. This is in strict accordance with Ohm's law.

## NEW BOOKS, ETC.

**THE MANUAL OF STATISTICS STOCK EXCHANGE HANDBOOK FOR 1910. New York: The Manual of Statistics Company, 1910. 12mo., 1086 pp. Price, $5.**

This volume, which is the thirty-second annual issue, deals with railroad securities, industrial securities, government securities, stock exchange quotations, mining, grain and provisions, cotton, money and information relative to bank and trust companies. It is accompanied by a number of well-executed maps and reference is made easy by the aid of thumb indexes. The book is a model compilation. Rarely have statistics been presented in clearer form. It is an indispensable handbook for the desk for all who are in any way interested in financial matters. There is hardly a person who does not have occasion at one time or another to refer to matters dealing more or less with the statistics of finance.

**DANBURY RODD AVIATOR. By Frederick Palmer. New York: Charles Scribner's Sons, 1910. 12mo., 310 pp. Price, $1.50.**

The average work of fiction devoted to any new science or sport is apt to be rather foolish, and in this respect Danbury Rodd is different from many of its predecessors. There is little question that the aeroplane has come to stay like the automobile, although its field of usefulness is rather more restricted. By far the best story of the eleven is entitled "A Cure by Aeroplane," in which a railway magnate is kidnapped, taken to his own island in the St. Lawrence River for a rest cure of a month. The book fairly reeks with gasoline, planes, propellers, trimming planes and all of the aeroplanist's patter. It is a very readable book and is certain to have an excellent sale. The book was brought out at a psychological moment.

**ALTITUDE TABLES. Computed for Intervals of Four Minutes Between the Parallels of Latitude 24 Deg. and 60 Deg. and Parallels of Declination 24 Deg. and 60 Deg. Designed for the Determination of the Position Line at All Hour Angles Without Logarithmic Computation. By Frederick Ball, M.A. London: J. D. Potter, 1909. 8vo., 43 pp.**

**THE NEW BAEDEKER. Casual Notes of an Irresponsible Traveler. By Harry Thurston Peck, Ph.D. New York: Dodd, Mead & Co., 1910. 12mo., 352 pp. Price, $1.50 net.**

Now that the "Scientific American Hand Book of Travel" is being purchased so largely by travelers who are thinking of making the voyage we feel that our readers will be more than interested in knowing of any new books on the subject. If you have ever been to Berlin, Utica, Atlantic City, Brussels, Winnipeg or any of the places written about by the Irresponsible Traveler, if you ever intend to visit them or feel any interest in them whatsoever, get a copy of "The New Baedeker." Almost as good as a visit to a place is the Irresponsible Traveler's light, humorous and yet wonderfully keen and adequate description of it. He tells about a little out-of-the-way bygone summer resort called Trenton Falls in a way that makes you vow you will go there. He formulates on paper the essence of Atlantic City. And there are chapters on Liverpool and on Havre which no transatlantic traveler, irresponsible or otherwise, should fail to read.

**AMERICAN SCHOOL GARDENS. By M. Louise Greene, M.Pd., Ph.D. New York: Charities Publication Committee, 1910. 12 mo., 388 pp. Price, $1.25.**

This is a publication of the Russell Sage Foundation and is a splendid example of how well the money of the late financier is being expended for the benefit of humanity. There is nothing which appeals to the imagination more than school gardens and the writer has taken special pains to visit some of these gardens. The book itself is handsomely gotten up and is admirably adapted to awaken a great interest in forming school gardens. There has been need of a manual as it were on this important subject and the author seems to have succeeded in producing a very thorough and scientific work. The bibliography alone is an imposing piece of work, while the list of various seeds, etc., which should be planted shows remarkable knowledge of the subject. The book is unquestionably based on personal observation and is beautifully illustrated with one hundred full-page and small half-tones. When publications of this kind are seen it makes one wish that more millionaires would leave their money with as much discretion as to the means by which it should be expended as did Mr. Sage.

**WORK ACCIDENTS AND THE LAW. By Crystal Eastman. New York: Charities Publication Committee, 1910. 8vo., 345 pp. Price, $1.50.**

This is a part of the Pittsburg Survey. The findings will be published in six volumes. A splendid work of this nature would be impossible were it not for the Russell Sage Foundation. A wiser expenditure of money could hardly have been devised. The study of industrial accidents and their betterment has attracted the attention of the foremost mechanical thinkers and industrial engineers. The editors of the principal technical papers in New

York are banded together to help support the American Museum of Safety This journal itself is vitally interested in the question of safety for industrial workers, safety on the railroads, and safety at sea The terrible loss of life and limb which is exacted each year as the industrial toll is something enormous. Each year 700,000 people in the United States, men, women and children, are either killed or maimed by accidents which in most cases are absolutely preventable There are, of course, certain accidents which may occur in heavy machinery which are the result of defects which cannot make themselves manifest during the progress of manufacture, but in the majority of cases it is possible to either prevent this industrial loss or to at least minimize it so that the damage is not so great. The book before us is one of the finest expositions we have ever seen of this twentieth century humanitarian interest The illustrations are clear cut and to the point and are beautifully executed The illustrations show what a cruel and deceptive looking place is a freight yard at night, with its ghastly white, green and red lights seemingly inextricably confused There are illustrations of the dangers which surround the workers in great metallurgical plants, also the great need of guards for the protection of wood working machinery The suggestions for prevention are many and are absolutely sound. The United States Steel Corporation has already expended large sums to safeguard their employees, and not from any selfish motive which is the best thing about the whole situation Plants all over the country are expending large sums to insure the safety of their employees, not with the idea that they will lessen the damage suits but from an earnest and honest desire to prevent the shocking industrial waste It is a small thing to put on the pay envelope "You are responsible for the safety of others as well as the safety of yourself" but a little sermonette of this kind often bears fruit The book has one of the best indexes we have ever seen, and the whole book is a great credit to everyone concerned

**The Unmasking of Robert-Houdin Together With a Treatise on Handcuff Secrets By Harry Houdini London George Routledge & Sons, Ltd, 1909 12mo.**

The author of this book is a well known performer on the vaudeville stage Unlike most men of his calling he takes a commendable historic and academic interest in it. We venture to say that he probably stands unique in that respect To perform the enormous amount of research which he has evidently conducted requires not only a love for the art of prestidigitation and magic but also expert knowledge Both of these Mr Houdini possesses to a marked degree After reading his book there can be no doubt that Robert Houdin brought very little to the art of conjuring that, like many conjurers, he was a more or less slavish imitator of those who were before him Although he makes no pretensions to literary excellence Mr Houdini has written a most fascinating book on a fascinating subject His historical researches he has supplemented with comments on his own performances which reveal how many of the handcuff tricks which astonish vaudeville spectators of to day are performed

**Oberammergau By Josephine Helena Short. New York Thomas Y Crowell & Co, 1910 16mo, 184 pp Price, $1 net.**

The object of this book is to give an intimate description of the village where the Passion Play is produced, of the people of the village and their everyday life with special attention to the characters chosen to take part in the sacred drama. The author has visited the locality at times when it was not thronged with tourists, and has established herself on terms of friendliness with the inhabitants A helpful résumé of the Passion Play is included in the volume, together with other information of value to visitors to Oberammergau and of interest to those who travel only through the medium of books The writer of this review has also had the great pleasure of seeing the Passion Play and he can certify to the completeness of the descriptions of both the place and the great religious drama that is enacted therein

**The World's Best Books. Suggestions for the Selection for a Home Library Cincinnati The Globe-Wernicke Company, 1909**

The book before us, which consists of some 37 pages luxuriously printed on beautiful paper, contains a carefully classified list of books desirable for the home library arranged appropriately Thus we find the one hundred best books of Sir John Lovatt Canon Farrar's list of twelve his list of five lists of best books for boys and girls the ten best novels twenty best novels novels of the West novels which picture English life novels of the sea problem novels, and lastly Dr Eliot's five-foot library and Roosevelt's pigskin library There is certainly very valuable information condensed in a short space By the by, the book is sent free of expense.

**Camp Cooking. By Horace Kephart. New York Outing Publishing Company, 1910 16mo., 154 pp. Price, $1**

At last we have a good book on camp cookery. The ordinary cook book would be very useless in a camp, as many of the ingredients could not readily be obtained. The book before us is one of the best cook books that have ever come to this reviewer's table. It gives precisely the information that is required, and in a scientific manner which is greatly to be commended The recipes are thoroughly common-sense, and include directions for cooking all kinds of dishes which smack of the woods, as deer's brain, moose muffle, venison sausages, jambolaya, "possum," fish baked in clay, and many other equally valuable dishes. Such ordinary articles of food as corn bread are also described The book is small and will readily slip in the pocket. It will not add a great deal to the weight. The slip cover is very handsome, and the photograph is worthy of better use.

## INDEX OF INVENTIONS

For which [illegible]

[illegible]
Pipe cleaner, F. R. Cunningham 961,215
Pipe coupling for cars, steam and air, R. R. Folsom [illegible]
Pipe coupling, train, Jewett & Greenlaw [illegible]
Pipe molding flask, J. R. McWane 961,367
Pipe nipple and clamp, O K Maxfield 961,347
Pipes and the like, regulating apparatus for hot water, R. Brakenbush 961,408
Pipes, apparatus for boring or laying drain, Lockhart & Jenkinson 961,244
Planter, picker for potato, C. H. Garling 961,436
Plow fender, J. P. Ertel [illegible]
Plow device, T. G. Tedesco [illegible]
Plow beam, J. B. McMillan [illegible]
Pole tip, R. N. Robinson [illegible]
Polishing machine, J. Pursehouse [illegible]
Post hole digger, W. L. Strickle [illegible]
Pot. See Coffee pot.
Potato cutting machine, seed, R. R. & M J. Lyster [illegible]
Potato digger, W. L. Skinner [illegible]
Power-driven machinery, D. C. Jackson [illegible]
Pressing device, F. A. Mills 961,180
Printer's galley, M. Corrigan [illegible]
Printing press, R. Pickering [illegible]
Printing press, T. Wislock [illegible]
Printing press, bed and cylinder, A. T. H. Brewer 961,208
Printing press, job, Trimbach & Allhoff [illegible]
Projectile, self propelling, W. T. Unge 961,170
Projection apparatus, W. L. Patterson [illegible]
Propeller, reversible, R. S. Bryant [illegible]
Propulsion apparatus, ship's, C. R. Mayhall [illegible]
Protecting pad or shield, W. H. McCormack [illegible]
Pulley rope gage, G. W. Mack 961,510
Pulverizing machine, sand, C. W. Herb 961,409
Pump, oscillating piston, M. Keller [illegible]
Pump, tire, C. E. Myers 961,152
Pump, wave operated, C. P. Bonney 961,411
Punching apparatus, A. J. Setter 961,053
Punching machine, Southworth & Spalding 961,251
Punching machines, clutch mechanism for, R. Southworth [illegible]
Pyroxylin compound, W. G. Lindsay [illegible]
Rail brace, W. S. Newhall [illegible]
Railway and car and appliances therefor, J. B. Fowler [illegible]
Railway brakes, means for operating, Neal & Childress 961,210
Railway rail antispreading device, T. B. Lindsley [illegible]
Railway rail joint, A. C. Richey [illegible]
Railway road bed construction, C. R. Holden [illegible]
Railway tie, F. Godward [illegible]
Railway tie, J. P. Boogher 961,476
Railway tie plate, A. Morrison 961,517
Razor case, safety, R. Middeldorf [illegible]
Razor stropping device, M. R. Crandall [illegible]
Reamer, expansion, Fouts & Hobbs 961,115
Receptacle for powder and the like, C. A. Turner 961,061
Reflector, electric light, G. F. Allen 961,196
Resilient connection device for relatively movable parts, Noles & Shepherd 961,512
Revolver safety device, J. H. Wesson 961,186, 961,189
Rod. See Curtain rod.
Roof bracket, S. P. Phoenix 961,648
Rosin purifying apparatus, R. N. Perlee 961,364
Route guides, ribbon maps, and the like, machine for operating, O. Ouliman [illegible]
Rubber heel, A. H. Heimbach [illegible]
Rubber heel, G. Hadlich [illegible]
Sad iron, F. R. Shafer 961,276
Sad iron, self heating, F. R. Shafer 961,277
Sash lock and burglar alarm, combined, Hoepel & Nordinger [illegible]
Sash, metal window, C. A. McGinnis 961,720
Sash, sheet metal, C. A. McGinnis 961,721
Saw clamp, F. A. Wuest [illegible]
Saw handle, detachable, D. A. Markwith [illegible]
Saw set, C. M. Larson [illegible]
Sawing machine, S. N. Krawchenko [illegible]
Scaffold bracket, C. F. Pinkley [illegible]
Scale, device for reproducing an object on a, G. F. Lattier [illegible]
[illegible]

Spraying machine, J. G. Martin 961,456
Spring wheel, G. H. Williams [illegible]
Station or street indicator, G. W. Lloyd [illegible]
Steam engine, H. W. Weaver 961,166
Steam generator, R. J. Galbraith [illegible]
Steam generator, G. M. L. Moore-Irvine 961,516
Stencils, manufacture of, W. H. Boone 961,579
Step or tread, F. H. Starwood 961,176
Storehouse, vegetable, J. R. Lafferty 961,464
Stovepipe and thimble, A. P. McGuirk 961,518
Strip cutter, A. J. Pierce 961,643
Sulfur chlorid, making, W. C. Quayle 961,530
Suspenders loop, overalls, C. E. Hawe 961,718
Switch chair, E. T. Robinson 961,261
Switch frog, H. F. Roach 961,533, 961,534
Tag holder, license, J. J. Thompson 961,267
Tapping device, barrel, A. M. Stork 961,739
Teeth treating decorated, F. M. Crane 961,287
Telegraph signals, apparatus for determining the direction of space, J. S. Stone 961,265
Telephone and testing instrument, portable, N. Macking 961,148
Telephone attachment, J. A. Perry 961,157
Tent suspended, C. R. Mark 961,704
Tentering machines, feeding device for, B. Parkinson 961,526
Testing device, J. Muchka 961,419
Thermo electric regulator, W. H. Mack 961,146
Ticket case, Hitchings & Fare 961,610
Tie. See Baling tie.
Tie plates or the like, manufacture of, J. S. York 961,608
Tightening device, G. T. Cunnius 961,688
Tile trimming machine, W. G. Trautvetter 961,560
Timer, D. W. Hare 961,407
Tire, R. Heyman 961,443
Tire holder and trunk, F. S. Sutherglen 961,553
Tire vehicle, J. C. Schleicher 961,374
Tires, composition of matter for repair of pneumatic, J. H. Lewis 961,144
Tires, means for automatically inflating pneumatic, R. Connell 961,104
Tires, mechanism for manufacturing pneumatic, T. Sloper 961,172
Tires, pressure regulating device for pneumatic, O. J. Brosnan 961,427
Tobacco leaves, stemming, J. O. Morris 961,740
Tobacco pipe, J. R. Perry 961,255
Tobacco stemming machine, J. O. Morris 961,638
Tool, Jordon & Sullivan 961,617
Tool, electrically heated, W. G. Clark 961,103
Tool holder, H. Batchelor 961,203
Tool, hollow, H. A. Hehrig 961,040
Torpedo shell, H. R. Lafferty 961,143
Toy book, J. W. Bevans 961,675
Toy handkerchief box, H. A. Young 961,431
Train control system, electrical block, J. B. Tonner 961,177
Tray, collapsible, H. M. Hays 961,228
Trowel, adjustable, R. W. Linville 961,302
Truck brake, R. D. Harding 961,404
Tube filling machine, R. M. & C. J. Clark 961,428
Tube forming machine, seamless, C. P. Higgins 961,128 to 961,133
Tube making apparatus, seamless, M. Allman 961,394
Tubes, mechanical joint for vacuum, D. M. Moore 961,101
Tubing, apparatus for hoisting, O. W. Olsen 961,420
Tug [illegible] for harness, equalizer, H. [illegible] 961,578
[illegible] W. A. Younie 961,598
[illegible] H. Wait 961,328, 961,329
[illegible] 961,206
[illegible] 961,451
[illegible] 961,712
[illegible] 961,546
[illegible] 961,528
[illegible] 961,647
[illegible] 961,701
[illegible] 961,194
[illegible] 961,202
[illegible] 961,288
[illegible] 961,290
[illegible] 961,307, 961,608
[illegible] 961,710
[illegible] 961,707
[illegible] 961,084
[illegible] 961,226

[illegible] 961,274
[illegible] 961,290
[illegible] 961,502
[illegible] 961,697
[illegible] 961,572
[illegible] 961,490
[illegible] 961,158
[illegible] B. Walters 961,300
[illegible] 961,277
Vending machine, [illegible] 961,694
Ventilator. See Window ventilator.
Vibrating screen or separator, T. I. & T. J. Sturtevant 961,487
Vibratory apparatus, valve operated mechanism for handles of, C. M. Siebert, Jr. 961,379
Voltage regulator, C. H. Johnson 961,411
Wagon brake, D. Mack 961,248
Wall tie or band, A. C. Decker 961,584
Walls, fastening means for, H. B. Jerauld 961,698
Washpail, G. H. Reeves 961,531
Watch holder for motor vehicles, H. T. Adams 961,071
Watchmaker's loop, W. Faustman 961,592
Water closet connection, J. J. Congrove 961,685
Water motor, R. B. Gamon 961,116
Water purifier and clarifier, J. E. Angell 961,091
Weather strip, adjustable, C. Anderson 961,363
Wedge, J. L. Thomas 961,725
Weight motor, J. A. Wilson 961,279
Wheelbarrow, J. M. Harris 961,609
Wheelbarrow, A. O. Hubbard 961,719
Windmill, A. M. Void 961,271
Windmill, J. A. Swanson 961,088
Windmill, L. O. Matthews 961,705
Window adjuster, casement, G. L. Wilkins 961,665
Window, double sliding sash, J. Mayr 961,726
Window fastening device, J. L. Mallory 961,627
Window ventilator, H. C. Russell 961,403
Wire drawing block, H. B. Humphrey 961,449
Wire holder, H. Holden 961,611
Wire stretcher and splicer, H. O. Jacobs 961,237
Wood, coloring and fireproofing, W. A. Hall 961,123
Wool, apparatus for removing the grease and yolk from, Vandaile & Lagye 961,468
Wrench, H. Henrichs 961,298
Wrench, A. C. Howe 961,447
Wrench, R. A. Montgomery 961,515
Wrench, G. R. Miller 961,632
Wrench, I. J. Benton 961,678
X-ray apparatus, A. Granger 961,697
Yarn and making same, J. G. Harrison 961,441
Stalkiferous substances, treating, G. Mejans 961,514

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

### MANGANESE STEEL RAILS.

*(Concluded from page 516)*

rails used by the Boston Elevated upon its curves were formed by casting. This is, of course, an expensive process. In fact, this corporation rail costs about $5 per foot for the rails. The ordinary rail costs only about 38 cents per foot, or only 1/3 as much. But even then it is regarded as a good investment, because of the very long life. In the autumn of 1908 the company had in service 475 feet of this rail in addition to three crossing frogs and a number of ordinary frogs. Its experience is certainly worthy of attention. However, if manganese steel can be rolled to advantage, we may expect a still better material at a lower figure. In fact, such rails have been rolled to sell for about $200 per ton, or about $2.50 per foot (about 85 pound section).

Perhaps a considerable portion of the expense of rolling manganese-steel rails is due to the considerable piping to which ingots of this material are subject, requiring thus a large discard or special means of prevention. On the other hand, considerable blow holes are thought to be infrequent, if they occur at all. This is attributed to the high percentage of substances which have a stronger affinity for oxygen than iron. This will be better understood, perhaps, by considering an analysis of manganese steel:

| | From | To |
|---|---|---|
| Manganese | 0.1100 | 0.1300 |
| Carbon | 0.0100 | 0.0120 |
| Silicon | 0.0025 | 0.0040 |
| Phosphorus | 0.0006 | 0.0011 |
| Sulphur | 0.0002 | 0.0006 |
| Iron | 0.8767 | 0.8523 |
| | 1.0000 | 1.0000 |

Some of the difficulties of rolling this metal have been given by Mr. W. S. Potter. When the temperature has fallen as low as about 1,300 deg. F., it becomes apparently inadvisable to continue, not merely because of the great difficulty of making reductions, but more especially because, when air-cooled afterward, the metal will be found to have a coarse structure and to be wanting in some of its desirable qualities. The steel may, however, be restored by reheating and quenching. However, we have then lost that excellence which results from rolling. Consequently, for the usual methods, 1,300 deg. F. is to be regarded as the lower limit. As to the upper limit—it is necessary to avoid burning or cracking, for the reason that then the steel will be apt to crush in the mill. Apparently, the upper limit beyond which it is scarcely safe to go is about 1,875 deg. F. We have then a thermal range of about 575 deg. F. in which to effect the rolling. But a rail ingot in the ordinary American practice has lost about 900 deg. F. by the time it has passed through the finishing rolls. Now it may be that manganese steel may cool somewhat more slowly than the ordinary rail steel. But we cannot expect the difference between 575 deg. and 900 deg. to be thus made up. So that, if we should proceed by the usual methods, we would be unable to secure our desired result. However, manganese steel has been successfully rolled in France, in England, and in the United States.

### HAMILTON'S AEROPLANE FLIGHT

*(Continued from page 521)*

by Curtiss in his trip down the Hudson—he quickly rose into the air and made a large circle over the island. When he left the shore and started to cross the Lower Bay four or five minutes had elapsed, so that the actual start was made at about 7:40. After flying across the bay and the Kill von Kull, Hamilton struck the line of the Pennsylvania Railroad at South Elizabeth, and followed it practically all the way to Philadelphia. The special train, bearing a white streamer on the roof of the foremost car, soon located him and caught up with

*(Continued on page 538.)*

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The Nat'l Co-op. Real Estate Co., Suite 378, Marden Building, Washington, D. C.

Inquiry No. 8818. For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

100 PER CENT profit selling the Lindsay soft inverted mantles; fit any inverted gasoline light. Steady customers in every town. Fine side line for salesmen. Vest pocket samples and prices on request. Lindsay Light Co., Dept. B, Chicago.

Inquiry No. 8887. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weser power meters.

## FOR SALE

FOR SALE.—Interest or control in manufacturing business. Exceptional opportunity for manager or instrument maker. Control, Box 773, N. Y.

Inquiry No. 9011.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE.—Factory building, brick, three stories, 26,000 sq. ft. floor. 80 h. p. steam engine. Cost to build over $18,000. Ground worth $3,000. Location 75 miles from Washington, D. C., on 2 railroads in city with large textile and vehicle factories. Abundance cheap electricity from hydraulic power. Shipments taken direct from factory platform by local freights. Cash price to quick purchaser $10,000. Send for photograph and description. F. S. Company, Box 773, N. Y.

Inquiry No. 9016. Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## PATENTS FOR SALE

FOR SALE.—Outright or on royalty, an automatic lock for miners safety lamps. Simple, can not be picked. For particulars address Anson Hall, Johnstown, Pa.

Inquiry No. 9020. Wanted catalogues and all information on machinery for braiding straw for manufacturing straw hats.

PATENT COMBINATION EYESHADE. Self adjustable to neatly fit any size or style spectacles. Folds in case and fits vest pocket. Glasses incomplete without one while reading. Just the thing for mail order. Samples 25 cents, postpaid. H. B. Henry, 3207 Girard Avenue, Philadelphia.

Inquiry No. 9028.—Wanted the address of the Lippman Electric Purifying Co.

FOR SALE. Patent No. 951,106. Outright or on royalty. Improvement in time alarms, especially adapted for timing telephone calls. J. W. Haywood, 621 E. 166th St., N. Y.

Inquiry No. 9050. Wanted to buy machinery to manufacture feed or n racks.

FOR SALE. Patent No. 959,664, as per notice in this issue of SCIENTIFIC AMERICAN. J. H. Melville, 69 Broadway, New York City.

Inquiry No. 9075. Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

FOR SALE. Patent No. 955,301. A machine on which one man does the work of a hundred (100). For further information address F. Rogowski, 2120 Frankfort Street, Chicago, Ill.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9078.—Wanted the address of manufacturers of sewer pipe made of fiber and asphaltum, suitable for laboratory use.

## SALE AND EXCHANGE

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $45.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9083. Wanted, the address of firms manufacturing small beer brewing plants from 75 to 100 gallons a day.

## MISCELLANEOUS.

WE are about to complete a large contract for Taxi meters and are therefore in a position to take up experimental work, manufacture of fine instruments, parts for the same, dies, jigs, etc. Precision Tool & Instrument Co., 9-15 Canal Place, New York City.

Inquiry No. 9091.—Wanted address of The Thomas Arithmometer Company, also Burkhart Arithmometer Company.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097. Wanted address of makers of impulse water wheels.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9107.—Wanted addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109. Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9113. Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9115. Wanted a machine for making pad nibs, similar to Wm. Mitchell's G. & J. nibs and Waverly pins.

Inquiry No. 9118. Wanted, a muffler for a gasoline engine built upon the principle of the Maxim silencer recently brought out for use on rifles.

Inquiry No. 9120.—Wanted, the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted manufacturers of cut stencils for fancy work, sofa pillows, etc. and oil colors and brushes for same.

Inquiry No. 9124.—Wanted name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9134.—Wanted, a small hydraulic motor, capable of giving about one horse power with a water power of 50 lbs. per square inch.

Inquiry No. 9135.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted, the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted, a device that will braid leather strips for horse whips.

Inquiry No. 9138.—Wanted the address of manufacturers of machines capable of forming a number (11 or more) of pieces of paste about 22 mm. x 22 mm. x 4 mm. made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139.—Wanted the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted, manufacturers of disc records for gramophones that use a sapphire point instead of a steel needle.

Inquiry No. 9142.—Wanted name and address of the manufacturers of an air mattress.

Inquiry No. 9144.—Wanted, manufacturers of machinery for making soda water tubes, commonly known as straws.

Inquiry No. 9145. Wanted to buy machinery to load blasting caps or detonators.

Inquiry No. 9149. Wanted, manufacturers of machinery for roasting coffee for small and large industries.

Inquiry No. 9150. Wanted, manufacturers of machinery for the manufacture of French heels for ladies' shoes.

Inquiry No. 9152. Wanted, the address of the Graham Safety Lamp Filler and Ventilator.

Inquiry No. 9153.—Wanted, name and address of manufacturers of a knotless clothes line.

Inquiry No. 9155. Wanted, the address of manufacturers of an electric milking machine.

Inquiry No. 9157.—Wanted, ...

Inquiry No. 91... peanut shelling and ...

Inquiry No. 91... grind oranges, pulp ... cream.

him, and for ten or ... directly over the tra... behind so that the ... catch him. Shortly ... delphia was reached he ... the train and, before ali..., he ma... two large circles above the field that was his destination.

The greater part of the trip Hamilton flew at a comparatively slight elevation—about 200 feet. Even in passing over the city of Trenton he rose to only double this height, as he preferred to take the chance of his motor stopping and of his being obliged to descend rather than to cut down his average speed by rising to a great elevation.

The various cities and towns along the route were passed upon schedule time.

After reaching the field at North Philadelphia and circling about a couple of times Hamilton alighted gracefully at 9 26 A. M., just 1 hour and 50 minutes from the time he started. If a deduction is made for the circling about at the start and finish, the actual time of the flight was about 1 hour and 45 minutes. The airline distance is 74.7 miles from Governor's Island to North Philadelphia, but over the route followed by Hamilton it was 82.9. The average speed, therefore, with the time of the circlings deducted, was 47.37 miles an hour, or 45.22, using the full time. In other words, Hamilton had started from an inaccessible island in New York harbor and traveled to North Philadelphia in considerably less time than one could accomplish this journey by boat to Jersey City and rail ...

... by special ... with ... boat and express train at ... possibilities of air communication ... forcibly demonstrated.

After being greeted by Governor Stuart and delivering to him the message, as shown in one of our illustrations, Hamilton refilled his fuel and oil tanks, and started on the return trip at 11:33 A. M. The special three-car train was delayed ten minutes in starting, and despite the fact that the train was driven at the fastest possible speed—80 miles an hour or more—its occupants did not catch sight of Hamilton until 23 minutes after they started, while it was about 10 minutes later before they finally overhauled him, 2 miles beyond Princeton Junction and 39 miles from the start. Thirty-seven miles had been covered by the special in 34 minutes, including a stop of 2 minutes at Bristol caused by an express train being in the way. The train and aeroplane traveled abreast of each other for a while, and finally Hamilton dropped slightly behind. He had covered the first 38 miles of his return journey at the rate of 51.8 miles an hour, thus making the fastest cross-country flight yet accomplished. At the small village of Plainsboro, 41 miles from North Philadelphia, Hamilton again flew over the tracks a thousand feet or more back of the train. The heavy clouds of smoke from the locomotive caused him to seek a higher elevation, and he rose to a height of about 800 feet. Soon after crossing the Raritan River the occupants of the train were surprised to see Hamilton turn off to the right and pass out of view. It seems he mistook the river for the Kill von Kull, and started, of course, toward what he supposed to be Governor's Island. The engine had been missing fire on several cylinders, and it finally was running on but six of its eight. Seeing what appeared to be a fine, smooth field below him, Hamilton decided to alight, but was quite dismayed to find himself in a marsh, from which the machine was dragged out with no little difficulty. In attempting to start, Hamilton again broke his propeller, and was obliged to send to Governor's Island for the only remaining one available. Several hours were consumed in getting this propeller—which, by the way, was the one that Curtiss used at Rheims in the Gordon Bennett race—but as soon as it arrived Hamilton immediately put it on and started once more, at 6 17 P. M. As the propeller was cracked and had been patched up with sheet tin, Hamilton feared it might break before he could complete his journey. He therefore rose to a considerable height—about 1,500 feet—and made a wide circle over Elizabeth. While above the city the engine again started missing and running on but six cylinders. Fortunately, however, his height was sufficient, so that he just succeeded in making Governor's Island during the course of his long descent. The 19¾ miles air-line distance from South Amboy to the Island was covered in about 23 minutes, and he finally alighted in front of the shed at 6 40 P. M.

In addition to this being probably the fastest cross-country flight ever executed, Hamilton's performance was a spectacular one, since the flight was made over water, cities, and open country. When news was received at New York that he had started on the return trip, thousands of people gathered at the Battery, expecting to see him arrive at Governor's Island at about 1 15 P. M. When word came that he had been forced to alight, the crowd was greatly disappointed. Nevertheless, there was a large crowd still when he finally crossed the Bay and alighted before sundown. The weather was humid and hazy, but the air was altogether calm. Hamilton was disappointed that he was unable to make the return trip without a stop. He would have been able to do this had it not been for motor troubles. As far as the aeroplane itself was concerned, this was well ...

(Concluded from page 528.)

... but Hamilton suffered from ... weakness of the aviator, a ... down. The motor does not seem to have been as thoroughly inspected as the rest of the machine, and the aviator has expressed the opinion that some missing piston rings in one or two of the cylinders allowed oil to escape by the piston and foul the spark plugs. There was no interruption in the sparking current supplied by the high-tension Bosch magneto. At any rate, Hamilton's flights showed the possibility of carrying mail and important dispatches, and it is interesting to note that Representative Shepherd of Texas has introduced a bill into Congress calling for the investigation of the Post Office Department into the aeroplane for the purpose of carrying mail. Also a few days after Hamilton's flight, the French war authorities commanded M. Blériot to carry a message from the camp of Chalons to Paris, which he did promptly in his monoplane without any mishap. During the present week Hamilton is to experiment for the government at Nashville, Tenn., upon the dropping of explosives from his machine. These experiments will be carried on during the maneuvers.

The flights of Curtiss and Hamilton have spurred many budding aviators to attempt in the near future some of the cross-country flights for prizes, and new prizes are being offered almost daily for such feats. We wish to remind such aviators that they stand a chance of winning the SCIENTIFIC AMERICAN Trophy if they send in their entry to us or to the Aero Club of America twenty-four hours in advance. The aviator making the longest cross-country flight this year will win the trophy for 1910.

## Emery.

BY WALTER C. COLD

There are three qualities of emery used in this country—Naxos or Greek, Turkish, and American.

The Naxos brand is imported from the island of Naxos (Grecian Archipelago), Greece, the mines being controlled by the Grecian government. Naxos emery contains a large percentage of alumina (about 65 per cent). This emery has a most excellent fracture, the grains being very hard and very sharp, and therefore especially adapted for use in grinding wheels. These characteristics prevent its use, to any extent, for polishing purposes, as it neither "breaks down" nor granulates under pressure of the work, as do the other qualities (Turkish and American). An ideal emery for polishing must present new cutting points constantly. The Naxos grains are so hard and sharp that it does not properly granulate, therefore it is not a desirable polishing medium, except for certain special classes of work. Naxos emery, owing to its large percentage of alumina, follows corundum in the scale of hardness.

Good Turkish emery contains any where from 15 per cent to 25 per cent oxide of iron (the larger the percentage of oxide of iron, the softer is the emery) and it is used therefore exclusively as a polisher on "hard work." Turkish emery has a good fracture, and is just tough enough to make it ideal for polishing purposes.

American emery contains about 45 per cent oxide of iron, and is therefore the softest emery produced, yet is successfully and largely used for certain classes of "soft work."

Most of the Naxos and Turkish emery brought to this country comes in pieces ranging from the size of a marble up to 25 or 30 pounds in weight. Formerly it was brought over as ballast in ships, but it became such an important commodity commercially, that during the last quarter century it has been transported across the water as regular cargo. Turkish emery is brought to the seaports of Asia Minor in the same primitive fashion which has existed for many years—on the back of camels. There are no up-to-date mining methods. The ore is taken from the surface only, and no attempt is made to follow the emery "leads" when they dip below the surface. Thus their mining methods are thoroughly characteristic of the inhabitants of the entire Turkish empire—crude and antiquated. Emery imported from Asia Minor is branded according to the seaport from which it is shipped, the seaports being Smyrna, Kulluk and Syra, the railway points are Knyujack, Alden, and Azizick. The different brands of course vary according to the purity of the emery—the larger the amount of oxide of alumina, the better the quality.

The American emery is mined near Peekskill, New York State. Some very excellent ore has been taken out at that place, but the bulk of the emery is high in oxide of iron and therefore soft. There is also a small deposit in the State of Kansas, but the deposit is insignificant and the quality of the emery of an inferior character.

The following are the physical properties of emery: Color black or blue black, specific gravity, 0.4050 ounce. It is thus placed in scale of hardness: Pure Naxos 8¾, pure Turkish 8½, pure American 8¼ (the diamond being No. 10).

In its manufacture the emery passes through great chilled rolls and crushed. It then passes over screens made from bolting cloth and from the screens it is packed directly into full kegs holding about 350 pounds, half kegs of about 175 pounds and quarter kegs of about 75 pounds, the number of the emery being determined by the mesh or number of holes in the cloth to the square inch. The principal numbers are as follows: 6, 8, 10, 12, 16, 24, 30, 36, 40, 46, 54, 60, 70, 80, 90, 100, 120, 140, 150, 160, 180, F, FF, FFF, FFFF. The first eleven numbers are what are termed "coarse grain," the second nine are the "fine grain," and the last four are "flours." In addition to these there are still finer flours. These are especially fine and used principally in optical work.

About 50 per cent of all emery is washed with water and then "blown" with a blower to remove the micaceous associates and other foreign matter. Emery so treated of course costs more to produce, but this treatment results in a pure article—one which will cut more keenly and be more durable than other wise.

Much improvement has taken place in the manufacture of emery in recent years, the principal innovation being the "concentrating" machine, through the use of which the emery is "mulled." This process also removes the micaceous associates and relieves the emery of low grade ore.

The consumption of emery in this country for both grinding wheels and polishing purposes, in 1909 was about 9,000 short tons or 18,000,000 pounds.

Emery is a commodity in the manufacturing world which is absolutely indispensable and the use of it is constantly increasing. There is no material for polishing purposes which could be successfully substituted for the reason that it is peculiarly fitted for this work. For polishing purposes corundum is too hard, on the other hand garnet, quartz, and flint are entirely unfitted—they lack that physical property of toughness which is possessed to a marked degree by emery.

It is stated in the Electrical World that of the 5,000,000 horse power actually represented by the Niagara Falls, only about 5.5 per cent, or about 270,000 horse power, has been thus far utilized. Of this, 126,000 horse-power is employed in electrochemical processes, 56,000 horse-power for railway service, 36,400 horse-power for lighting, and 45,500 horse-power for various industrial services. Nearly 125,000 horse-power is transmitted to points more than ten miles from the falls. Of this amount 12,300 horse-power is transmitted over a distance of more than 100 miles, while 33,500 horse power is transmitted between 75 and 100 miles.
